Legal Disclaimer

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (www.infineon.com).

Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.

Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

Table of Contents

| | | |
|----------|--|------------|
| 1 | Introduction | 1-1 |
| 1.1 | Overview | 1-1 |
| 1.1.1 | Block Diagram | 1-3 |
| 1.2 | Core Processing Units | 1-3 |
| 1.2.1 | Central Processing Unit (CPU) | 1-4 |
| 1.2.2 | Programmable Multiple Priority Interrupt System (NVIC) | 1-4 |
| 1.3 | System Units | 1-4 |
| 1.3.1 | Memories | 1-4 |
| 1.3.2 | Watchdog Timer (WDT) | 1-4 |
| 1.3.3 | Real Timer Clock (RTC) | 1-5 |
| 1.3.4 | System Control unit (SCU) | 1-5 |
| 1.3.5 | Pseudo Random Bit Generator (PRNG) | 1-5 |
| 1.4 | Peripherals Units | 1-5 |
| 1.5 | Debug Unit | 1-6 |
| 2 | Central Processing Unit (CPU) | 2-1 |
| 2.1 | Overview | 2-1 |
| 2.1.1 | Features | 2-2 |
| 2.1.2 | Block Diagram | 2-2 |
| 2.2 | Programmers Model | 2-3 |
| 2.2.1 | Processor Mode | 2-3 |
| 2.2.2 | Stacks | 2-3 |
| 2.2.3 | Core Registers | 2-5 |
| 2.2.4 | Exceptions and Interrupts | 2-15 |
| 2.2.5 | Data Types | 2-15 |
| 2.2.6 | The Cortex Microcontroller Software Interface Standard | 2-15 |
| 2.2.7 | CMSIS Functions | 2-16 |
| 2.3 | Memory Model | 2-18 |
| 2.3.1 | Memory Regions, Types and Attributes | 2-19 |
| 2.3.2 | Memory System Ordering of Memory Accesses | 2-19 |
| 2.3.3 | Behavior of Memory Accesses | 2-20 |
| 2.3.4 | Software Ordering of Memory Accesses | 2-21 |
| 2.3.5 | Memory Endianness | 2-22 |
| 2.3.5.1 | Little-endian format | 2-22 |
| 2.4 | Instruction Set | 2-23 |
| 2.4.1 | Intrinsic Functions | 2-25 |
| 2.5 | Exception Model | 2-26 |
| 2.5.1 | Exception States | 2-26 |
| 2.5.2 | Exception Types | 2-27 |
| 2.5.3 | Exception Handlers | 2-28 |
| 2.5.4 | Vector Table | 2-28 |

Table of Contents

| | | |
|----------|---|------------|
| 2.5.4.1 | Vector Table Remap | 2-29 |
| 2.5.5 | Exception Priorities | 2-30 |
| 2.5.6 | Exception Entry and Return | 2-31 |
| 2.5.6.1 | Exception entry | 2-32 |
| 2.5.6.2 | Exception return | 2-34 |
| 2.6 | Fault Handling | 2-35 |
| 2.6.1 | Lockup | 2-35 |
| 2.7 | Power Management | 2-36 |
| 2.7.1 | Entering Sleep Mode | 2-36 |
| 2.7.2 | Wakeup from Sleep Mode | 2-37 |
| 2.7.3 | Power Management Programming Hints | 2-37 |
| 2.8 | Private Peripherals | 2-38 |
| 2.8.1 | About the Private Peripherals | 2-38 |
| 2.8.2 | System control block | 2-38 |
| 2.8.2.1 | System control block usage hints and tips | 2-38 |
| 2.8.3 | System timer, SysTick | 2-38 |
| 2.8.3.1 | SysTick usage hints and tips | 2-39 |
| 2.9 | PPB Registers | 2-40 |
| 2.9.1 | SCS Registers | 2-41 |
| 2.9.2 | SysTick Registers | 2-52 |
| 3 | Bus System | 3-1 |
| 3.1 | Bus Interfaces | 3-1 |
| 4 | Service Request Processing | 4-1 |
| 4.1 | Overview | 4-1 |
| 4.1.1 | Features | 4-1 |
| 4.1.2 | Block Diagram | 4-1 |
| 4.2 | Service Request Distribution | 4-3 |
| 5 | Interrupt Subsystem | 5-1 |
| 5.1 | Nested Vectored Interrupt Controller (NVIC) | 5-1 |
| 5.1.1 | Features | 5-1 |
| 5.1.2 | Interrupt Node Assignment | 5-1 |
| 5.1.3 | Interrupt Signal Generation | 5-2 |
| 5.1.4 | NVIC design hints and tips | 5-3 |
| 5.1.5 | Accessing CPU Registers using CMSIS | 5-3 |
| 5.1.6 | Interrupt Priority | 5-4 |
| 5.1.7 | Interrupt Latency | 5-5 |
| 5.2 | General Module Interrupt Structure | 5-6 |
| 5.3 | Registers | 5-8 |
| 5.3.1 | NVIC Registers | 5-9 |
| 5.4 | Interrupt Request Source Overview | 5-13 |
| 6 | Event Request Unit (ERU) | 6-1 |

Table of Contents

| | | |
|----------|--|------------|
| 6.1 | Features | 6-1 |
| 6.2 | Overview | 6-1 |
| 6.3 | Event Request Select Unit (ERS) | 6-2 |
| 6.4 | Event Trigger Logic (ETLx) | 6-3 |
| 6.5 | Cross Connect Matrix | 6-4 |
| 6.6 | Output Gating Unit (OGUy) | 6-5 |
| 6.7 | Power, Reset and Clock | 6-8 |
| 6.8 | Initialization and System Dependencies | 6-9 |
| 6.9 | Registers | 6-10 |
| 6.9.1 | ERU Registers | 6-11 |
| 6.10 | Interconnects | 6-16 |
| 6.10.1 | ERU0 Connections | 6-17 |
| 7 | Memory Organization | 7-1 |
| 7.1 | Overview | 7-1 |
| 7.1.1 | Features | 7-1 |
| 7.1.2 | Cortex-M0 Address Space | 7-1 |
| 7.2 | Memory Regions | 7-2 |
| 7.3 | Memory Map | 7-3 |
| 7.4 | Memory Access | 7-9 |
| 7.4.1 | Flash Memory Access | 7-9 |
| 7.4.2 | SRAM Access | 7-9 |
| 7.4.3 | ROM Access | 7-9 |
| 7.5 | Memory Protection Strategy | 7-9 |
| 7.5.1 | Intellectual Property (IP) Protection | 7-10 |
| 7.5.1.1 | Blocking of Unauthorized External Access | 7-10 |
| 7.5.2 | Memory Access Protection during Run-time | 7-10 |
| 7.5.2.1 | Bit Protection Scheme | 7-10 |
| 7.5.2.2 | Peripheral Privilege Access Control | 7-12 |
| 7.6 | Service Request Generation | 7-12 |
| 7.7 | Debug Behaviour | 7-13 |
| 7.8 | Power, Reset and Clock | 7-13 |
| 7.9 | Initialization and System Dependencies | 7-13 |
| 8 | Flash Architecture | 8-1 |
| 8.1 | Overview | 8-1 |
| 8.1.1 | Features | 8-1 |
| 8.2 | Definitions | 8-1 |
| 8.2.1 | Logical and Physical States | 8-2 |
| 8.2.2 | Data Portions | 8-2 |
| 8.2.3 | Address Types | 8-3 |
| 8.2.4 | Module Specific Definitions | 8-3 |
| 8.3 | Module Components | 8-3 |
| 8.3.1 | Memory Cell Array | 8-4 |

Table of Contents

| | | |
|----------|--|------------|
| 8.3.1.1 | Page | 8-4 |
| 8.3.1.2 | Sector | 8-5 |
| 8.4 | Functional Description | 8-5 |
| 8.4.1 | SFR Accesses | 8-5 |
| 8.4.2 | Memory Read | 8-5 |
| 8.4.2.1 | Flash read access with fixed wait states | 8-5 |
| 8.4.3 | Memory Write | 8-6 |
| 8.4.4 | Memory Erase | 8-7 |
| 8.4.5 | Sector Erase | 8-7 |
| 8.4.6 | Verify | 8-8 |
| 8.4.7 | Erase-Protection and Write-Protection | 8-8 |
| 8.5 | Redundancy | 8-8 |
| 8.6 | Properties and Implementation of Error Correcting Code (ECC) | 8-9 |
| 8.7 | Service Request Generation | 8-9 |
| 8.8 | Power, Reset and Clock | 8-9 |
| 8.8.1 | Power Supply | 8-9 |
| 8.8.2 | Power Saving Modes | 8-9 |
| 8.8.2.1 | NVM Idle Mode | 8-10 |
| 8.8.2.2 | NVM Sleep Mode | 8-10 |
| 8.8.3 | Reset | 8-10 |
| 8.8.4 | Clock | 8-10 |
| 8.9 | Registers | 8-11 |
| 8.9.1 | NVM Registers | 8-12 |
| 8.10 | Example Sequences | 8-19 |
| 8.10.1 | Writing to Memory | 8-19 |
| 8.10.1.1 | Writing a Single Block | 8-19 |
| 8.10.1.2 | Writing Blocks | 8-19 |
| 8.10.2 | Erasing Memory | 8-20 |
| 8.10.2.1 | Erasing a Single Page | 8-20 |
| 8.10.2.2 | Erasing Pages | 8-20 |
| 8.10.2.3 | Erasing a Single Sector | 8-20 |
| 8.10.2.4 | Erasing Sectors | 8-21 |
| 8.10.3 | Verifying Memory | 8-21 |
| 8.10.3.1 | Verifying a Single Block | 8-21 |
| 8.10.3.2 | Verifying Blocks | 8-21 |
| 8.10.4 | Writing to an Already Written Block | 8-22 |
| 8.10.5 | Sleep Mode | 8-24 |
| 8.10.6 | Timing | 8-25 |
| 9 | Peripheral Access Unit (PAU) | 9-1 |
| 9.1 | Overview | 9-1 |
| 9.1.1 | Features | 9-1 |
| 9.2 | Peripheral Privilege Access Control | 9-1 |

Table of Contents

| | | |
|-----------|--|-------------|
| 9.3 | Peripheral Availability and Memory Size | 9-2 |
| 9.4 | Service Request Generation | 9-2 |
| 9.5 | Debug Behaviour | 9-2 |
| 9.6 | Power, Reset and Clock | 9-2 |
| 9.7 | Initialization and System Dependencies | 9-2 |
| 9.8 | PAU Registers | 9-2 |
| 9.8.1 | Peripheral Privilege Access Registers (PRIVDISn) | 9-3 |
| 9.8.2 | Peripheral Availability Registers (AVAILn) | 9-6 |
| 9.8.3 | Memory Size Registers | 9-9 |
| 10 | Window Watchdog Timer (WDT) | 10-1 |
| 10.1 | Overview | 10-1 |
| 10.1.1 | Features | 10-1 |
| 10.1.2 | Block Diagram | 10-2 |
| 10.2 | Time-Out Mode | 10-3 |
| 10.3 | Pre-warning Mode | 10-3 |
| 10.4 | Bad Service Operation | 10-4 |
| 10.5 | Service Request Processing | 10-6 |
| 10.6 | Debug Behavior | 10-6 |
| 10.7 | Power, Reset and Clock | 10-6 |
| 10.8 | Initialization and Control Sequence | 10-6 |
| 10.8.1 | Initialization & Start of Operation | 10-6 |
| 10.8.2 | Software Stop & Resume Operation | 10-7 |
| 10.8.3 | Enter Sleep/Deep-Sleep & Resume Operation | 10-7 |
| 10.8.4 | Pre-warning Alarm Handling | 10-8 |
| 10.9 | WDT Registers | 10-9 |
| 10.9.1 | Registers Description | 10-9 |
| 10.10 | Interconnects | 10-16 |
| 11 | Real Time Clock (RTC) | 11-1 |
| 11.1 | Overview | 11-1 |
| 11.1.1 | Features | 11-1 |
| 11.1.2 | Block Diagram | 11-1 |
| 11.2 | RTC Operation | 11-2 |
| 11.3 | Register Access Operations | 11-3 |
| 11.4 | Service Request Processing | 11-4 |
| 11.4.1 | Periodic Service Request | 11-4 |
| 11.4.2 | Timer Alarm Service Request | 11-4 |
| 11.5 | Debug Behavior | 11-4 |
| 11.6 | Power, Reset and Clock | 11-4 |
| 11.7 | Initialization and Control Sequence | 11-5 |
| 11.7.1 | Initialization & Start of Operation | 11-5 |
| 11.7.2 | Configure and Enable Periodic Event | 11-5 |
| 11.7.3 | Configure and Enable Timer Event | 11-5 |

Table of Contents

| | | |
|-----------|--|-------------|
| 11.8 | RTC Registers | 11-6 |
| 11.8.1 | Registers Description | 11-7 |
| 11.9 | Interconnects | 11-17 |
| 12 | System Control Unit (SCU) | 12-1 |
| 12.1 | Overview | 12-1 |
| 12.1.1 | Features | 12-1 |
| 12.1.2 | Block Diagram | 12-2 |
| 12.2 | Miscellaneous Control Functions (GCU) | 12-4 |
| 12.2.1 | Service Requests Handling | 12-4 |
| 12.2.1.1 | Service Request Sources | 12-4 |
| 12.2.2 | SRAM Memory Content Protection | 12-5 |
| 12.2.3 | Summary of ID | 12-6 |
| 12.3 | Power Management (PCU) | 12-8 |
| 12.3.1 | Functional Description | 12-8 |
| 12.3.2 | System States | 12-8 |
| 12.3.3 | Embedded Voltage Regulator (EVR) | 12-10 |
| 12.3.4 | Power-on Reset | 12-10 |
| 12.3.5 | Power Validation | 12-10 |
| 12.3.6 | Supply Voltage Monitoring | 12-10 |
| 12.3.7 | V _{DDC} Response During Load Change | 12-11 |
| 12.3.8 | Flash Power Control | 12-12 |
| 12.4 | Reset Control (RCU) | 12-13 |
| 12.4.1 | Functional Description | 12-13 |
| 12.4.2 | Reset Status | 12-14 |
| 12.5 | Clock Control (CCU) | 12-15 |
| 12.5.1 | Features | 12-15 |
| 12.5.2 | Clock System and Control | 12-15 |
| 12.5.2.1 | Oscillator Watchdog | 12-18 |
| 12.5.2.2 | Loss of Clock Detection and Recovery | 12-18 |
| 12.5.2.3 | Standby Clock Failure | 12-19 |
| 12.5.2.4 | Startup Control for System Clock | 12-19 |
| 12.5.3 | Clock Gating Control | 12-19 |
| 12.5.4 | Calibrating DCO based on Temperature | 12-20 |
| 12.6 | Service Request Generation | 12-21 |
| 12.7 | Debug Behavior | 12-21 |
| 12.8 | Power, Reset and Clock | 12-21 |
| 12.9 | Registers | 12-23 |
| 12.9.1 | PCU Registers (ANACTRL) | 12-25 |
| 12.9.2 | PCU Registers (SCU) | 12-26 |
| 12.9.3 | CCU Registers (SCU) | 12-27 |
| 12.9.4 | CCU Registers (ANACTRL) | 12-34 |
| 12.9.5 | RCU Registers (SCU) | 12-35 |

Table of Contents

| | | |
|-----------|--|-------------|
| 12.9.6 | GCU Registers (SCU) | 12-39 |
| 13 | Pseudo Random Number Generator (PRNG) | 13-1 |
| 13.1 | Overview | 13-1 |
| 13.1.1 | Features | 13-1 |
| 13.2 | Description of Operation Modes | 13-1 |
| 13.2.1 | Key Loading Mode | 13-1 |
| 13.2.2 | Streaming Mode | 13-2 |
| 13.2.3 | Refreshing and Restarting a Random Bit Stream | 13-2 |
| 13.3 | Service Request Generation | 13-3 |
| 13.4 | Debug Behavior | 13-3 |
| 13.5 | Power, Reset and Clock | 13-3 |
| 13.6 | Initialization and System Dependencies | 13-3 |
| 13.7 | Registers | 13-3 |
| 13.7.1 | Data Registers | 13-4 |
| 13.7.2 | Control Registers | 13-6 |
| 14 | Universal Serial Interface Channel (USIC) | 14-1 |
| 14.1 | Overview | 14-1 |
| 14.1.1 | Features | 14-1 |
| 14.2 | Operating the USIC | 14-6 |
| 14.2.1 | USIC Structure Overview | 14-6 |
| 14.2.1.1 | Channel Structure | 14-6 |
| 14.2.1.2 | Input Stages | 14-6 |
| 14.2.1.3 | Output Signals | 14-8 |
| 14.2.1.4 | Baud Rate Generator | 14-9 |
| 14.2.1.5 | Channel Events and Interrupts | 14-10 |
| 14.2.1.6 | Data Shifting and Handling | 14-10 |
| 14.2.2 | Operating the USIC Communication Channel | 14-14 |
| 14.2.2.1 | Protocol Control and Status | 14-15 |
| 14.2.2.2 | Mode Control | 14-16 |
| 14.2.2.3 | General Channel Events and Interrupts | 14-17 |
| 14.2.2.4 | Data Transfer Events and Interrupts | 14-18 |
| 14.2.2.5 | Baud Rate Generator Event and Interrupt | 14-20 |
| 14.2.2.6 | Protocol-specific Events and Interrupts | 14-22 |
| 14.2.3 | Operating the Input Stages | 14-22 |
| 14.2.3.1 | General Input Structure | 14-23 |
| 14.2.3.2 | Digital Filter | 14-25 |
| 14.2.3.3 | Edge Detection | 14-25 |
| 14.2.3.4 | Selected Input Monitoring | 14-26 |
| 14.2.3.5 | Loop Back Mode | 14-26 |
| 14.2.4 | Operating the Baud Rate Generator | 14-26 |
| 14.2.4.1 | Fractional Divider | 14-26 |
| 14.2.4.2 | External Frequency Input | 14-27 |

Table of Contents

| | | |
|-----------|---|-------|
| 14.2.4.3 | Divider Mode Counter | 14-27 |
| 14.2.4.4 | Capture Mode Timer | 14-28 |
| 14.2.4.5 | Time Quanta Counter | 14-29 |
| 14.2.4.6 | Master and Shift Clock Output Configuration | 14-30 |
| 14.2.5 | Operating the Transmit Data Path | 14-31 |
| 14.2.5.1 | Transmit Buffering | 14-31 |
| 14.2.5.2 | Transmit Data Shift Mode | 14-32 |
| 14.2.5.3 | Transmit Control Information | 14-33 |
| 14.2.5.4 | Transmit Data Validation | 14-34 |
| 14.2.6 | Operating the Receive Data Path | 14-36 |
| 14.2.6.1 | Receive Buffering | 14-36 |
| 14.2.6.2 | Receive Data Shift Mode | 14-37 |
| 14.2.6.3 | Baud Rate Constraints | 14-38 |
| 14.2.7 | Hardware Port Control | 14-38 |
| 14.2.8 | Operating the FIFO Data Buffer | 14-39 |
| 14.2.8.1 | FIFO Buffer Partitioning | 14-40 |
| 14.2.8.2 | Transmit Buffer Events and Interrupts | 14-41 |
| 14.2.8.3 | Receive Buffer Events and Interrupts | 14-45 |
| 14.2.8.4 | FIFO Buffer Bypass | 14-50 |
| 14.2.8.5 | FIFO Access Constraints | 14-51 |
| 14.2.8.6 | Handling of FIFO Transmit Control Information | 14-52 |
| 14.3 | Asynchronous Serial Channel (ASC = UART) | 14-54 |
| 14.3.1 | Signal Description | 14-54 |
| 14.3.2 | Frame Format | 14-55 |
| 14.3.2.1 | Idle Time | 14-56 |
| 14.3.2.2 | Start Bit Detection | 14-57 |
| 14.3.2.3 | Data Field | 14-57 |
| 14.3.2.4 | Parity Bit | 14-57 |
| 14.3.2.5 | Stop Bit(s) | 14-57 |
| 14.3.3 | Operating the ASC | 14-58 |
| 14.3.3.1 | Bit Timing | 14-58 |
| 14.3.3.2 | Baud Rate Generation | 14-59 |
| 14.3.3.3 | Noise Detection | 14-60 |
| 14.3.3.4 | Collision Detection | 14-60 |
| 14.3.3.5 | Pulse Shaping | 14-60 |
| 14.3.3.6 | Automatic Shadow Mechanism | 14-62 |
| 14.3.3.7 | End of Frame Control | 14-62 |
| 14.3.3.8 | Mode Control Behavior | 14-63 |
| 14.3.3.9 | Disabling ASC Mode | 14-63 |
| 14.3.3.10 | Protocol Interrupt Events | 14-63 |
| 14.3.3.11 | Data Transfer Interrupt Handling | 14-64 |
| 14.3.3.12 | Baud Rate Generator Interrupt Handling | 14-64 |
| 14.3.3.13 | Protocol-Related Argument and Error | 14-65 |

Table of Contents

| | | |
|-----------|---|--------|
| 14.3.3.14 | Receive Buffer Handling | 14-65 |
| 14.3.3.15 | Sync-Break Detection | 14-65 |
| 14.3.3.16 | Transfer Status Indication | 14-65 |
| 14.3.4 | ASC Protocol Registers | 14-66 |
| 14.3.4.1 | ASC Protocol Control Register | 14-66 |
| 14.3.4.2 | ASC Protocol Status Register | 14-69 |
| 14.3.5 | Hardware LIN Support | 14-72 |
| 14.4 | Synchronous Serial Channel (SSC) | 14-74 |
| 14.4.1 | Signal Description | 14-74 |
| 14.4.1.1 | Transmit and Receive Data Signals | 14-76 |

| 21.8.9 | DWT_MASKx - DWT Comparator Mask Register | 21-33 |
| 21.8.10 | DWT_FUNCTIONx - Comparator Function Register | 21-34 |
| 21.8.11 | BP_CTRL - Breakpoint Control Register | 21-35 |
| 21.8.12 | Breakpoint Comparator Registers | 21-36 |

About this Document

This Reference Manual is addressed to embedded hardware and software developers. It provides the reader with detailed descriptions about the behavior of the XMC1100 series functional units and their interaction.

The manual describes the functionality of the superset device of the XMC1100 microcontroller series. For the available functionality (features) of a specific XMC1100 derivative (derivative device), please refer to the respective Data Sheet. For simplicity, the various device types are referenced by the collective term XMC1100 throughout this manual.

XMC1000 Family User Documentation

The set of user documentation includes:

- **Reference Manual**
 - describes the functionality of the superset device.
- **Data Sheets**
 - list the complete ordering information, available features and electrical characteristics of derivative devices.
- **Errata Sheets**
 - list deviations from the specifications given in the related Reference Manual or Data Sheets. Errata Sheets are provided for the superset of devices.

Attention: Please consult all parts of the documentation set to attain consolidated knowledge about your device.

Application related guidance is provided by **Users Guides** and **Application Notes**.

Text Conventions

This document uses the following naming conventions:

- Functional units of the XMC1100 are given in plain UPPER CASE. For example: "The USIC0 unit supports..."
- Pins using negative logic are indicated by an overline. For example: "The $\overline{\text{WAIT}}$ input has..."
- Bit fields and bits in registers are in general referenced as "Module_RegisterName.BitField" or "Module_RegisterName.Bit". For example: "The USIC0_PCR.MCLK bit enables the...". Most of the register names contain a module name prefix, separated by an underscore character "_" from the actual register name (for example, "USIC0_PCR", where "USIC0" is the module name prefix, and "PCR" is the kernel register name). In chapters describing the kernels of the peripheral modules, the registers are mainly referenced with their kernel register names. The peripheral module implementation sections mainly refer to the actual register names with module prefixes.
- Variables used to describe sets of processing units or registers appear in mixed upper and lower cases. For example, register name "MOFCR_n" refers to multiple "MOFCR" registers with variable n. The bounds of the variables are always given where the register expression is first used (for example, "n = 0-31"), and are repeated as needed in the rest of the text.
- The default radix is decimal. Hexadecimal constants are suffixed with a subscript letter "H", as in 100_H. Binary constants are suffixed with a subscript letter "B", as in 111_B.
- When the extent of register fields, groups register bits, or groups of pins are collectively named in the body of the document, they are represented as "NAME[A:B]", which defines a range for the named group from B to A. Individual bits, signals, or pins are given as "NAME[C]" where the range of the variable C is given in the text. For example: CFG[2:0] and SRPN[0].
- Units are abbreviated as follows:
 - **MHz** = Megahertz
 - **μs** = Microseconds
 - **kBaud, kbit** = 1000 characters/bits per second
 - **MBaud, Mbit** = 1,000,000 characters/bits per second
 - **Kbyte, KB** = 1024 bytes of memory
 - **Mbyte, MB** = 1048576 bytes of memory

In general, the k prefix scales a unit by 1000 whereas the K prefix scales a unit by 1024. Hence, the Kbyte unit scales the expression preceding it by 1024. The kBaud unit scales the expression preceding it by 1000. The M prefix scales by 1,000,000 or 1048576. For example, 1 Kbyte is 1024 bytes, 1 Mbyte is 1024 × 1024 bytes, 1 kBaud/kbit are 1000 characters/bits per second, 1 MBaud/Mbit are 1000000 characters/bits per second, and 1 MHz is 1,000,000 Hz.

- Data format quantities are defined as follows:
 - **Byte** = 8-bit quantity
 - **Half-word** = 16-bit quantity
 - **Word** = 32-bit quantity
 - **Double-word** = 64-bit quantity

Bit Function Terminology

In tables where register bits or bit fields are defined, the following conventions are used to indicate the access types.

Table 1 Bit Function Terminology

| Bit Function | Description |
|--------------|---|
| rw | The bit or bit field can be read and written. |
| rwh | As rw, but bit or bit field can be also set or reset by hardware. If not otherwise documented the software takes priority in case of a write conflict between software and hardware. |
| r | The bit or bit field can only be read (read-only). |
| w | The bit or bit field can only be written (write-only). A read to this register will always give a default value back. |
| rh | This bit or bit field can be modified by hardware (read-hardware, typical example: status flags). A read of this bit or bit field give the actual status of this bit or bit field back. Writing to this bit or bit field has no effect to the setting of this bit or bit field. |

Register Access Modes

Read and write access to registers and memory locations are sometimes restricted. In memory and register access tables, the following terms are used.

Table 2 Register Access Modes

| Symbol | Description |
|------------|--|
| PV (SV), U | Access permitted in Privileged (Supervisor) Mode. Note: ARM® Cortex M0 processor does not support different privilege levels. Only Privileged (Supervisor) Mode is supported in XMC1000 Family. Symbol “U” and Symbol “PV” can be used to represent the access permitted in this mode. |
| BP | Indicates that this register can only be access when the bit protection is disabled. See detailed description of Bit Protection Scheme in the Memory Organisation chapter. |

Table 2 Register Access Modes (cont'd)

| Symbol | Description |
|--------|---|
| 32 | Only 32-bit word accesses are permitted to this register/address range. |
| NC | No change, indicated register is not changed. |
| BE | Indicates that an access to this address range generates a Bus Error. |
| nBE | Indicates that no Bus Error is generated when accessing this address range. |

Reserved Bits

Register bit fields named **Reserved** or **0** indicate unimplemented functions with the following behavior.

- Reading these bit fields returns 0.
- These bit fields should be written with 0 if the bit field is defined as r or rh.
- These bit fields have to be written with 0 if the bit field is defined as rw.

These bit fields are reserved. The detailed description of these bit fields can be found in the register descriptions.

Abbreviations and Acronyms

The following acronyms and terms are used in this document:

Introduction

1 Introduction

The XMC1100 series belongs to the XMC1000 Family of industrial microcontrollers based on the ARM Cortex-M0 processor core. The XMC1100 series devices are designed for general purpose applications.

Increasing complexity and demand for computing power of embedded control applications requires microcontrollers to have a significant CPU performance, integrated peripheral functionality and rapid development environment enabling short time-to-market, without compromising cost efficiency. Nonetheless the architecture of the XMC1100 microcontroller pursue successful hardware and software concepts, which have been established in Infineon microcontroller families.

1.1 Overview

The XMC1100 series devices combine the extended functionality and performance of the Cortex-M0 core with powerful on-chip peripheral subsystems and on-chip memory units. The following key features are available within the range of XMC1100 series devices:

CPU Subsystem

- CPU Core
 - High Performance 32-bit Cortex-M0 CPU
 - Most of 16-bit Thumb instruction set
 - Subset of 32-bit Thumb2 instruction set
 - High code density with 32-bit performance
 - Single cycle 32-bit hardware multiplier
 - System timer (SysTick) for Operating System support
 - Ultra low power consumption
- Nested Vectored Interrupt Controller (NVIC)
- Event Request Unit (ERU) for programmable processing of external and internal service requests

On-Chip Memories

- 8 kbytes on-chip ROM
- 16 kbytes on-chip high-speed SRAM
- up to 64 kbytes on-chip Flash program and data memory

System Control and Peripherals

- Universal Serial Interface Channels (USIC), usable as UART, double-SPI, quad-SPI, IIC, IIS and LIN interfaces
- A/D Converters, up to 12 channels, includes a 12-bit analog to digital converter
- Capture/Compare Units 4 (CCU4) for use as general purpose timers
- Window Watchdog Timer (WDT) for safety sensitive applications
- Real Time Clock module with alarm support (RTC)
- System Control Unit (SCU) for system configuration and control
- Temperature Sensor (TSE)
- Pseudo random number generator (PRNG), provides random data with fast generation times

Input/Output Lines With Individual Bit Controllability

- Tri-stated in input mode
- Push/pull or open drain output mode
- Configurable pad hysteresis

Debug System

- Access through the standard ARM serial wire debug (SWD) or the single pin debug (SPD) interface
- A breakpoint unit (BPU) supporting up to 4 hardware breakpoints
- A watchpoint unit (DWT) supporting up to 2 watchpoints

Packages Information

- PG-VQFN-40
- PG-VQFN-24
- PG-TSSOP-38
- PG-TSSOP-16

Note: For details about package availability for a particular derivative please check the datasheet.

1.1.1 Block Diagram

The diagram below shows the functional blocks and their basic connectivity within the XMC1100 System.

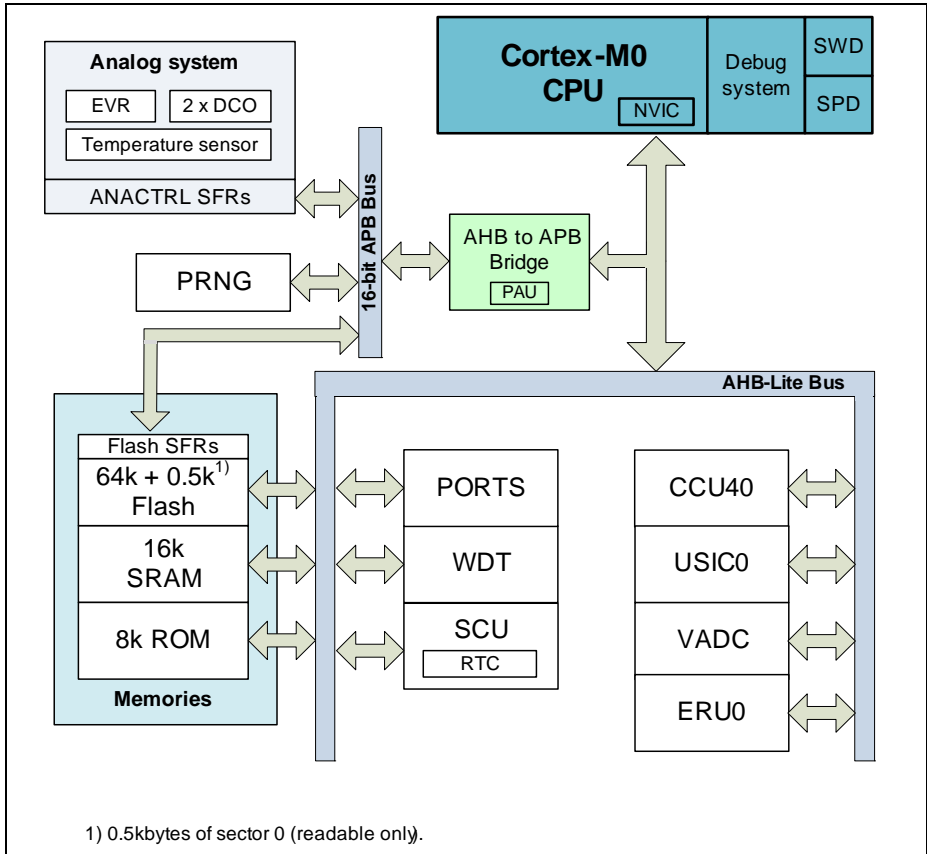

Figure 1-1 XMC1100 Functional diagram

1.2 Core Processing Units

The XMC1100 system core consists of the CPU and the memory interface blocks for memories.

1.2.1 Central Processing Unit (CPU)

The ARM Cortex-M0 processor is built on a highly area and power optimized 32-bit processor core, with a 3-stage pipeline von Neumann architecture. The processor delivers exceptional energy efficiency through a small but powerful instruction set and extensively optimized design, providing high-end processing hardware including a single cycle multiplier.

The instruction set is based on the 16-bit Thumb instruction set and includes Thumb-2 technology. This provides the exceptional performance expected of a modern 32-bit architecture, with a higher code density than other 8-bit and 16-bit microcontrollers.

1.2.2 Programmable Multiple Priority Interrupt System (NVIC)

The XMC1100 provides separate interrupt nodes that may be assigned to 4 interrupt priority levels. Most interrupt sources are connected to a dedicated interrupt node. In some cases, multi-source interrupt nodes are incorporated for efficient use of system resources. These nodes can be activated by several source requests and are controlled via interrupt subnode control registers.

1.3 System Units

The XMC1100 controllers provide a number of system resources designed around the CPU.

1.3.1 Memories

8 kbytes of ROM (ROM) memory for boot code execution and exception vector table. The ROM contains system basic initialization sequence code and is executed immediately after reset release. The Bootstrap Loaders(BSL) and User Routines are also stored in the ROM.

Up to 64 kbytes of on-chip Flash memory store code or constant data. Dynamic error correction provides high read data security for all read accesses.

16 kbytes of on-chip code RAM (SRAM) are provided to store user code or data, as well as system variables such as system stack. The SRAM is accessed via the AHB and provides zero-waitstate access for CPU code execution.

1.3.2 Watchdog Timer (WDT)

The main purpose of the Window Watchdog Timer is to improve the system integrity. WDT triggers the system reset or other corrective action like e.g. an interrupt if the main program, due to some fault condition, neglects to regularly service the watchdog. The intention is to bring the system back from the unresponsive state into normal operation.

1.3.3 Real Timer Clock (RTC)

Real-time clock (RTC) is a clock that keeps track of the current time. RTCs are present in almost any electronic device which needs to keep accurate time in a digital format for clock displays and computer systems..

1.3.4 System Control unit (SCU)

The System Control Unit (SCU) handles all system control tasks besides the debug related tasks. All functions are tightly coupled and thus, they are conveniently handled by one unit, SCU. It consists of the Power Control Unit (PCU), Reset Control Unit, Clock Control Unit (CCU) and the Miscellaneous Control Unit (GCU).

The CCU generates the Main clock (MCLK) and the fast Peripheral clock (PCLK) using the 64MHz DCO1 oscillator. The PCU has a Embedded Voltage Regulator (EVR) that is used to generate the core voltage. It also provides voltage monitoring detectors to secure system performance under critical condition (eg. brownout).

1.3.5 Pseudo Random Bit Generator (PRNG)

The pseudo random bit generator (PRNG) provides random data with fast generation times.

1.4 Peripherals Units

XMC1100 offers a set of on-chip peripherals to support industrial applications.

Universal Serial Interface Channel (USIC)

The USIC is a flexible interface module covering several serial communication protocols such as ASC, LIN, SSC, I2C, I2S. A USIC module contains two independent communication channels which can be used in parallel. A FIFO allows transmit and result buffering for relaxing real-time conditions. Multiple chip select signals are available for communication with multiple devices on the same channel.

Analog to Digital Converter (VADC)

The Versatile Analog-to-Digital Converter module consists of an independent kernels which operate according to the successive approximation principle (SAR). The resolution is programmable from 8 to 12bit.

The kernel provides a versatile state machine allowing complex measurement sequences. The kernels can be synchronized and conversions may run completely in background. Multiple trigger events can be prioritized and allow the exact measurement of time critical signals. The result buffering and handling avoids data loss and ensures consistency. Self-test mechanisms can be used for plausibility checks.

Introduction

The basic structure supports a clean software architecture where tasks may only read valid results and do not need to care for starting conversions.

Capture/Compare Unit 4 (CCU4)

The CCU4 peripheral is a major component for systems that need general purpose timers for signal monitoring/conditioning and Pulse Width Modulation (PWM) signal generation. Power electronic control systems like switched mode power supplies or uninterruptible power supplies can easily be implemented with the functions inside the CCU4 peripheral.

The internal modularity of CCU4 translates into a software friendly system for fast code development and portability between applications.

General Purpose I/O Ports (PORTS)

The Ports provide a generic and very flexible software and hardware interface for all standard digital I/Os. Each Port slice has individual interfaces for the operation as General Purpose I/O and it further provides the connectivity to the on-chip periphery and the control for the pad characteristics.

Temperature Sensor (TSE)

The Temperature Sensor generates a measurement result that indicates directly the die temperature. It is also capable of generating interrupt requests when the temperature measurement crosses the selectable upper/lower threshold value.

1.5 Debug Unit

The on-chip debug system based on the ARM Cortex-M0™ debug system provides a broad range of debug and emulation features built into the XMC1100. The user software running on the XMC1100 can thus be debugged within the target system environment.

The Debug unit is controlled by an external debugging tool via the debug interface. The debugger controls the Debug unit via a set of dedicated registers accessible via the debug interface. Additionally, the Debug unit can be controlled by the CPU, e.g. by a monitor program.

Multiple breakpoints can be triggered by on-chip hardware or by software. Single stepping is supported as well as the injection of arbitrary instructions and read/write access to the complete internal address space. A breakpoint trigger can be answered with a CPU-halt, a monitor call or a data transfer.

The data transferred at a watchpoint (see above) can be obtained via the debug interface for increased performance.

CPU Subsystem

2 Central Processing Unit (CPU)

XMC1100 features the ARM Cortex-M0 processor. An entry-level 32-bit ARM Cortex processor designed for a broad range of embedded applications. This CPU offers significant benefits to users, including:

- a simple architecture that is easy to learn and program
- ultra-low power, energy efficient operation
- excellent code density
- deterministic, high-performance interrupt handling
- upward compatibility with Cortex-M processor family

2.1 Overview

The Cortex-M0 processor is built on a highly area and power optimized 32-bit processor core, with a 3-stage pipeline von Neumann architecture. The processor delivers exceptional energy efficiency through a small but powerful instruction set and extensively optimized design, providing high-end processing hardware including a single-cycle multiplier.

The Cortex-M0 processor implements the ARMv6-M architecture, which is based on the 16-bit Thumb® instruction set and includes Thumb-2 technology. The Cortex-M0 instruction set provides exceptional performance expected of a modern 32-bit architecture, with a higher code density than other 8-bit and 16-bit microcontrollers.

The Cortex-M0 processor closely integrates a configurable NVIC, to deliver industry leading interrupt performance. The NVIC provides 4 interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing the interrupt latency. This is achieved through the hardware stacking of registers, and the ability to abandon and restart load-multiple and store-multiple operations. Interrupt handlers do not require any assembler wrapper code, removing any code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another.

Central Processing Unit (CPU)

To optimize low-power designs, the NVIC integrates with the sleep modes, that include a deep sleep function that enables the entire device to be rapidly powered down.

2.1.1 Features

The CPU provides the following functionality:

- Thumb instruction set combines high code density with 32-bit performance
- integrated sleep modes for low power consumption
- fast code execution permits slower processor clock or increases sleep mode time
- single cycle 32-bit hardware multiplier
- high-performance interrupt handling for time-critical applications
- extensive debug capabilities:
 - Serial Wire Debug and Single Pin Debug reduce the number of pins required for debugging.

2.1.2 Block Diagram

The Cortex-M0 core components comprise of:

Processor Core

The CPU provides most 16-bit Thumb instruction set and subset of 32-bit Thumb2 instruction set.

Nested Vectored Interrupt Controller

The NVIC is an embedded interrupt controller that supports low latency interrupt processing.

Debug Solution

The XMC1100 implements a complete hardware debug solution.

- Single Pin Debug (SPD) or 2-pin Serial Wire Debug (SWD)
- Extensive hardware breakpoint and watchpoint options

This provides high system control and visibility of the processor and memory even in small package devices.

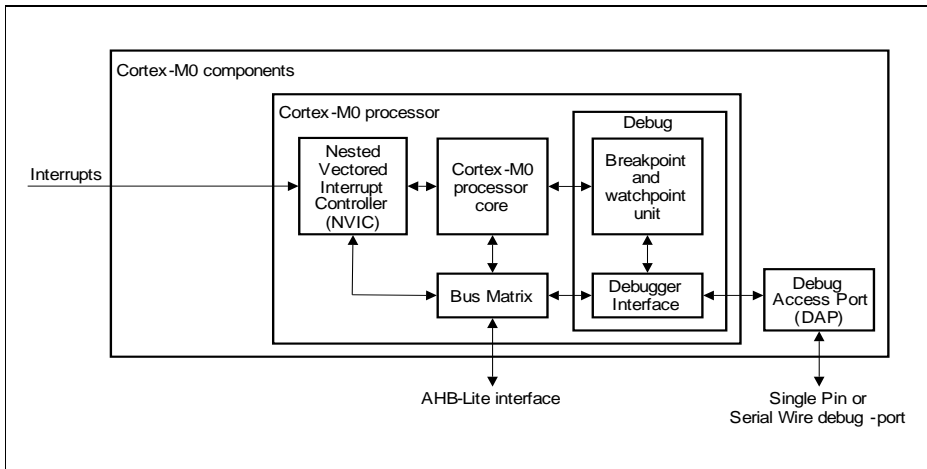

Figure 2-1 Cortex-M0 Block Diagram

System Level Interface

The Cortex-M0 processor provides a single system-level interface using AMBA® technology to provide high speed, low latency memory accesses.

2.2 Programmers Model

This section describes the Cortex-M0 programmers model. In addition to the individual core register descriptions, it contains information about the processor modes and stacks.

2.2.1 Processor Mode

The processor modes are:

- **Thread mode**
Used to execute application software. The processor enters Thread mode when it comes out of reset.
- **Handler mode**
Used to handle exceptions. The processor returns to Thread mode when it has finished all exception processing.

2.2.2 Stacks

The processor uses a full descending stack. This means the stack pointer holds the address of the last stacked item in memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory

Central Processing Unit (CPU)

location. The processor implements two stacks, the main stack and the process stack, with a pointer for each held in independent registers, see [Stack Pointer](#).

In Thread mode, the CONTROL register controls whether the processor uses the main stack or the process stack, see [CONTROL Register](#). In Handler mode, the processor always uses the main stack. The options for processor operations are:

Table 2-1 Summary of processor mode, execution, and stack use options

| Processor mode | Used to execute | Stack used |
|-----------------------|------------------------|---|
| Thread | Applications | Main stack or process stack ¹⁾ |
| Handler | Exception handlers | Main stack |

1) See [CONTROL Register](#).

2.2.3 Core Registers

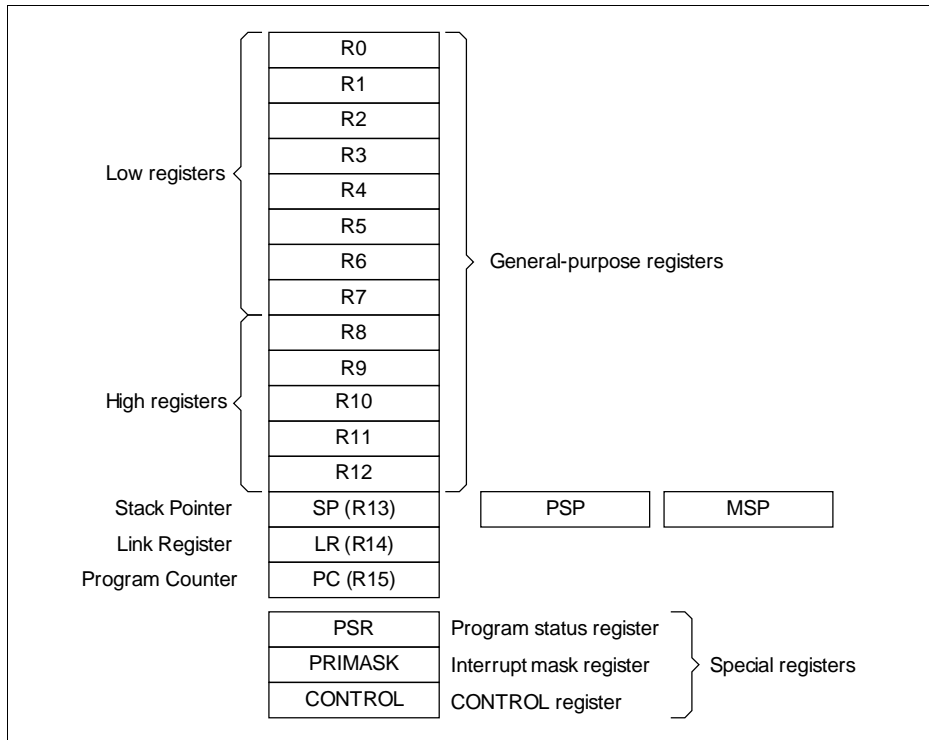

Figure 2-2 Core registers

The processor core registers are:

Table 2-2 Core register set summary

| Name | Type ¹⁾ | Reset value | Description |
|--------|--------------------|-----------------|---|
| R0-R12 | rw | Unknown | General-purpose registers on Page 2-6 |
| MSP | rw | See description | Stack Pointer on Page 2-6 |

| CONTROL | rw | 00000000 _H | CONTROL Register on Page 2-14 |

1) Describes access type during program execution in thread mode and handler mode. Debug access can differ.

General-purpose registers

R0-R12 are 32-bit general-purpose registers for data operations.

Note: For information on how to program the core registers, please refer to the ARMv6-M Architecture Reference Manual [2].

Rx (x=0-12)

General-purpose register Rx

Reset Value: XXXXXXXX_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| Value | [31:0] | rw | Content of Register |

Stack Pointer

The Stack Pointer (SP) is register R13. In Thread mode, bit[1] of the CONTROL register indicates the stack pointer to use:

- 0 = Main Stack Pointer (MSP). This is the reset value.

Central Processing Unit (CPU)

- 1 = Process Stack Pointer (PSP).

On reset, the processor loads the MSP with the value from address 00000000_H.

Note: For information on how to program the core registers, please refer to the ARMv6-M Architecture Reference Manual [2].

SP

Stack Pointer

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| Value | [31:0] | rw | Content of Register |

Link Register

The Link Register (LR) is register R14. It stores the return information for subroutines, function calls, and exceptions. On reset, the LR value is unknown.

Note: For information on how to program the core registers, please refer to the ARMv6-M Architecture Reference Manual [2].

LR

Link Register

Reset Value: XXXXXXXX_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| Value | [31:0] | rw | Content of Register |

Program Counter

The Program Counter (PC) is register R15. It contains the current program address. On reset, the processor loads the PC with the value of the reset vector, which is at address 00000004_H. Bit [0] of the value is loaded into the EPSR T-bit at reset and must be 1.

Note: For information on how to program the core registers, please refer to the ARMv6-M Architecture Reference Manual [2].

PC

Program Counter

Reset Value: 00000004_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| Value | [31:0] | rw | Content of Register |

Program Status Register

The Program Status Register (PSR) combines:

- Application Program Status Register (APSR)
- Interrupt Program Status Register (IPSR)
- Execution Program Status Register (EPSR)

These registers are mutually exclusive bit fields in the 32-bit PSR.

Access these registers individually or as a combination of any two or all three registers, using the register name as an argument to the MSR or MRS instructions. For example:

- read all of the registers using PSR with the MRS instruction
- write to the APSR N, Z, C, and V bits using APSR with the MSR instruction

The PSR combinations and attributes are:

Table 2-3 PSR register combinations

| Register | Type | Combination |
|----------|--------------------|----------------------|
| PSR | rw ¹⁾²⁾ | APSR, EPSR, and IPSR |
| IEPSR | r | EPSR and IPSR |
| IAPSR | rw ¹⁾ | APSR and IPSR |
| EAPSR | rw ²⁾ | APSR and EPSR |

1) The processor ignores writes to the IPSR bits.

2) Reads of the EPSR bits return zero, and the processor ignores writes to the these bits

Application Program Status Register

The APSR contains the current state of the condition flags from previous instruction executions. See the register summary in [Table 2-2](#) for its attributes.

APSR

Application Program Status Register

Reset Value: XXXXXXXX_H

| Field | Bits | Type | Description |
|----------|--------|------|-----------------------------|
| N | 31 | rw | Negative flag |
| Z | 30 | rw | Zero flag |
| C | 29 | rw | Carry or borrow flag |
| V | 28 | rw | Overflow flag |
| 0 | [27:0] | r | Reserved |

Central Processing Unit (CPU)

Interrupt Program Status Register

The IPSR contains the exception type number of the current Interrupt Service Routine (ISR). See the register summary in [Table 2-2](#) for its attributes.

IPSR

Interrupt Program Status Register

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|-------------|
| 0 | [31:6] | r | Reserved |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|-------------------|-------|------|--|
| ISR_NUMBER | [5:0] | r | Number of the current exception 0 _D Thread mode 1 _D Reserved 2 _D Reserved 3 _D HardFault 4 _D Reserved 5 _D Reserved 6 _D Reserved 7 _D Reserved 8 _D Reserved 9 _D Reserved 10 _D Reserved 11 _D SVCall 12 _D Reserved 13 _D Reserved 14 _D PendSV 15 _D SysTick 16 _D IRQ0 ... 47 _D IRQ31 48 _D -63 _D Reserved See Exception types in Section 2.5.2 for more information. |

Execution Program Status Register

The EPSR contains the Thumb state bit.

See the register summary in [Table 2-2](#) for the EPSR attributes.

Attempts to read the EPSR directly through application software using the MSR instruction always return zero. Attempts to write the EPSR using the MSR instruction in application software are ignored. Fault handlers can examine the EPSR value in the stacked PSR to determine the cause of the fault. See Exception Entry and Return in [Section 2.5.6](#).

EPSR

Execution Program Status Register

Reset Value: XXXXXXXX_H

| Field | Bits | Type | Description |
|-------|---------|------|-------------------------------------|
| 0 | [31:25] | r | Reserved |
| T | 24 | r | Thumb state bit See Thumb state. |
| 0 | [23:0] | r | Reserved |

Interruptible-restartable instructions

When an interrupt occurs during the execution of an LDM, STM, PUSH, POP instruction, the processor abandons execution of the instruction.

After servicing the interrupt, the processor restarts execution of the instruction from the beginning.

Thumb state

The Cortex-M0 processor only supports execution of instructions in Thumb state. The following can clear the T bit to 0:

- instructions BLX, BX and POP{PC}

Central Processing Unit (CPU)

- restoration from the stacked xPSR value on an exception return
- bit[0] of the vector value on an exception entry.

Attempting to execute instructions when the T bit is 0 results in a HardFault or lockup. See Lockup in [Section 2.6.1](#) for more information.

Exception mask registers

The exception mask registers disable the handling of exceptions by the processor. Disable exceptions where they might impact on timing critical tasks or code sequences requiring atomicity.

Exceptions can be disabled or re-enabled by the MSR and MRS instructions, or the CPS instruction, to change the value of PRIMASK or FAULTMASK.

Priority Mask Register

The PRIMASK register prevents activation of all exceptions with configurable priority. See the register summary in [Table 2-2](#) for its attributes.

PRIMASK

Priority Mask Register

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|---------|--------|------|---|
| 0 | [31:1] | r | Reserved |
| PRIMASK | 0 | rw | Priority Mask 0 _B No effect. 1 _B Prevents the activation of all exceptions with configurable priority. |

Central Processing Unit (CPU)

CONTROL Register

The CONTROL register controls the stack used when the processor is in Thread mode. See the register summary in [Table 2-2](#) for its attributes.

CONTROL

CONTROL Register

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| 0 | [31:2] | r | Reserved |
| SPSEL | 1 | rw | Active stack pointer This bit defines the current stack. In Handler mode, this bit reads as zero and ignores writes. 0 _B MSP is the current stack pointer 1 _B PSP is the current stack pointer |
| 0 | 0 | r | Reserved |

Handler mode always uses the MSP, so the processor ignores explicit writes to the active stack pointer bit of the CONTROL register when in Handler mode. The exception entry and return mechanisms automatically update the CONTROL register.

In an OS environment, it is recommended that threads running in Thread mode use the process stack and the kernel and exception handlers use the main stack.

By default, Thread mode uses the MSP. To switch the stack pointer used in Thread mode to the PSP, use the MSR instruction to set the Active stack pointer bit to 1.

Note: When changing the stack pointer, software must use an ISB instruction immediately after the MSR instruction. This ensures that instructions after the ISB instruction execute using the new stack pointer.

2.2.4 Exceptions and Interrupts

The Cortex-M0 processor supports interrupts and system exceptions. The processor and the NVIC prioritize and handle all exceptions. An interrupt or exception changes the normal flow of software control. The processor uses handler mode to handle all exceptions except for reset. See Exception entry on [Section 2.5.6.1](#) and Exception return on [Section 2.5.6.2](#) for more information.

The NVIC registers control interrupt handling. See Interrupt System chapter for more information.

2.2.5 Data Types

The processor:

- supports the following data types:
 - 32-bit words
 - 16-bit halfwords
 - 8-bit bytes
- manages all data memory accesses as little-endian. See Memory regions, types and attributes in [Section 2.3.1](#) for more information.

2.2.6 The Cortex Microcontroller Software Interface Standard

For a Cortex-M0 microcontroller system, the Cortex Microcontroller Software Interface Standard (CMSIS) [\[3\]](#) defines:

- a common way to:
 - access peripheral registers
 - define exception vectors
- the names of:
 - the registers of the core peripherals
 - the core exception vectors
- a device-independent interface for RTOS kernels.

The CMSIS includes address definitions and data structures for the core peripherals in the Cortex-M0 processor.

CMSIS simplifies software development by enabling the reuse of template code and the combination of CMSIS-compliant software components from various middleware vendors. Software vendors can expand the CMSIS to include their peripheral definitions and access functions for those peripherals.

This document includes the register names defined by the CMSIS, and gives short descriptions of the CMSIS functions that address the processor core and the core peripherals.

Central Processing Unit (CPU)

Note: This document uses the register short names defined by the CMSIS. In a few cases these differ from the architectural short names that might be used in other documents.

The following sections give more information about the CMSIS:

- Power Management Programming Hints in [Section 2.7.3](#)
- CMSIS Functions in [Section 2.2.7](#)
- Accessing CPU Registers using CMSIS in Interrupt System chapter
- NVIC programming hints in Interrupt System chapter

For additional information please refer to <http://www.onarm.com/cmsis>

2.2.7 CMSIS Functions

ISO/IEC C code cannot directly access some Cortex-M0 instructions. This section describes intrinsic functions that can generate these instructions, provided by the CMSIS and that might be provided by a C compiler. If a C compiler does not support an appropriate intrinsic function, an inline assembler may be used to access the relevant instruction.

The CMSIS provides the following intrinsic functions to generate instructions that ISO/IEC C code cannot directly access:

Table 2-4 CMSIS functions to generate some Cortex-M0 instructions

| Instruction | CMSIS intrinsic function |
|-------------|---------------------------------------|
| CPSIE i | void __enable_irq (void) |
| CPSID i | void __disable_irq (void) |
| ISB | void __ISB (void) |
| DSB | void __DSB (void) |
| DMB | void __DMB (void) |
| NOP | void __NOP (void) |
| REV | uint32_t __REV (uint32_t int value) |
| REV16 | uint32_t __REV16 (uint32_t int value) |
| REVSH | uint32_t __REVSH (uint32_t int value) |
| WFE | void __WFE (void) |
| WFI | void __WFI (void) |

The CMSIS also provides a number of functions for accessing the special registers using MRS and MSR instructions:

Table 2-5 CMSIS functions to access the special registers

| Special register | Access | CMSIS function |
|-------------------------|---------------|--|
| PRIMASK | Read | uint32_t __get_PRIMASK (void) |
| | Write | void __set_PRIMASK (uint32_t value) |
| CONTROL | Read | uint32_t __get_CONTROL (void) |
| | Write | void __set_CONTROL (uint32_t value) |
| MSP | Read | uint32_t __get_MSP (void) |
| | Write | void __set_MSP (uint32_t TopOfMainStack) |
| PSP | Read | uint32_t __get_PSP (void) |
| | Write | void __set_PSP (uint32_t TopOfMainStack) |

Central Processing Unit (CPU)

2.3 Memory Model

This section describes the processor memory map and the behavior of memory accesses. The processor has a fixed default memory map that provides up to 4GB of addressable memory. The memory map is:

| | | |
|------------------------|-------|--------------------------|
| Device | 511MB | 0xFFFFFFFF |
| Private peripheral bus | 1.0MB | 0xE0100000 0xE00FFFFF |
| External device | 1.0GB | 0xE0000000 0xDFFFFFFF |
| External RAM | 1.0GB | 0xA0000000 0x9FFFFFFF |
| Peripheral | 0.5GB | 0x60000000 0x5FFFFFFF |
| SRAM | 0.5GB | 0x40000000 0x3FFFFFFF |
| Code | 0.5GB | 0x20000000 0x1FFFFFFF |
| | | 0x00000000 |

Figure 2-3 Memory map

Central Processing Unit (CPU)

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers, see About the Private Peripherals in [Section 2.8.1](#).

2.3.1 Memory Regions, Types and Attributes

The memory map is split into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

| | |
|-------------------------|--|
| Normal | The processor can re-order transactions for efficiency, or perform speculative reads. |
| Device | The processor preserves transaction order relative to other transactions to Device or Strongly-ordered memory. |
| Strongly-ordered | The processor preserves transaction order relative to all other transactions. |

The different ordering requirements for Device and Strongly-ordered memory mean that the memory system can buffer a write to Device memory, but must not buffer a write to Strongly-ordered memory.

The additional memory attributes include:

| | |
|---------------------------|---|
| Execute Never (XN) | Means the processor prevents instruction accesses. A HardFault exception is generated on execution of an instruction fetched from an XN region of memory. |
|---------------------------|---|

2.3.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing any re-ordering does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions, see Software ordering of memory accesses in [Section 2.3.4](#).

However, the memory system does guarantee some ordering of accesses to Device and Strongly-ordered memory. For two memory access instructions A1 and A2, if A1 occurs before A2 in program order, the ordering of the memory accesses caused by two instructions is described in [Figure 2-4](#).

| A1 \ A2 | Normal access | Device access | Strongly-ordered access |
|-------------------------|---------------|---------------|-------------------------|
| Normal access | - | - | - |
| Device access | - | < | < |
| Strongly-ordered access | - | < | < |

Figure 2-4 Memory system ordering

Where:

- “-” Means that the memory system does not guarantee the ordering of the accesses.
- “<” Means that accesses are observed in program order, that is, A1 is always observed before A2.

2.3.3 Behavior of Memory Accesses

The behavior of accesses to each region in the memory map is:

Table 2-6 Memory access behavior

| Address range | Memory region | Memory type ¹⁾ | XN ¹⁾ | Description |
|-----------------------|-----------------|---------------------------|------------------|--|
| 0x00000000-0x1FFFFFFF | Code | Normal | - | Executable region for program code. Data can be placed here. |
| 0x20000000-0x3FFFFFFF | SRAM | Normal | - | Executable region for data. Code can be placed here. |
| 0x40000000-0x5FFFFFFF | Peripheral | Device | XN | Peripherals region. |
| 0x60000000-0x9FFFFFFF | External RAM | Normal | - | Executable region for data. |
| 0xA0000000-0xDFFFFFFF | External device | Device | XN | External device memory. |

Central Processing Unit (CPU)

Table 2-6 Memory access behavior (cont'd)

| Address range | Memory region | Memory type ¹⁾ | XN ¹⁾ | Description |
|-----------------------|------------------------|---------------------------|------------------|---|
| 0xE0000000-0xE00FFFFF | Private Peripheral Bus | Strongly-ordered | XN | This region includes the NVIC, system timer, and system control block. Only word accesses can be used in this region. |
| 0xE0100000-0xFFFFFFFF | Device | Device | XN | Vendor specific |

1) See Memory regions, types and attributes in [Section 2.3.1](#) for more information.

The Code, SRAM, and external RAM regions can hold programs.

2.3.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions. This is because:

- the processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- memory or devices in the memory map have different wait states
- some memory accesses are buffered or speculative.

Memory system ordering of memory accesses in [Section 2.3.2](#) describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The processor provides the following memory barrier instructions:

| | |
|------------|--|
| DMB | The Data Memory Barrier (DMB) instruction ensures that outstanding memory transactions complete before subsequent memory transactions. |
| DSB | The Data Synchronization Barrier (DSB) instruction ensures that outstanding memory transactions complete before subsequent instructions execute. |
| ISB | The Instruction Synchronization Barrier (ISB) ensures that the effect of all completed memory transactions is recognizable by subsequent instructions. |

2.3.5 Memory Endianness

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. [Section 2.3.5.1](#) describes how words of data are stored in memory.

2.3.5.1 Little-endian format

In little-endian format, the processor stores the least significant byte (lsbyte) of a word at the lowest-numbered byte, and the most significant byte (msbyte) at the highest-numbered byte. An example of the little-endian format is described in [Figure 2-5](#).

Figure 2-5 Little-endian format (Example)

2.4 Instruction Set

Table 2-7 lists the supported Cortex-M0 instructions. For more information on the instructions and operands, please refer to the Cortex™-M0 Devices, Generic User Guide available through [\[1\]](#).

Table 2-7 Cortex-M0 instructions

| Mnemonic | Operands | Brief description | Flags |
|----------|------------------------|---|---------|
| ADCS | {Rd,} Rn, Rm | Add with carry | N,Z,C,V |
| ADD{S} | {Rd,} Rn, <Rm #imm> | Add | N,Z,C,V |
| ADR | Rd, label | PC-relative Address to Register | - |
| ANDS | {Rd,} Rn, Rm | Bitwise AND | N,Z |
| ASRS | {Rd,} Rm, <Rs #imm> | Arithmetic Shift Right | N,Z,C |
| B{cc} | label | Branch {conditionally} | - |
| BICS | {Rd,} Rn, Rm | Bit Clear | N,Z |
| BKPT | #imm | Breakpoint | - |
| BL | label | Branch with Link | - |
| BLX | Rm | Branch indirect with Link | - |
| BX | Rm | Branch indirect | - |
| CMN | Rn, Rm | Compare Negative | N,Z,C,V |
| CMP | Rn, <Rm #imm> | Compare | N,Z,C,V |
| CPSID | i | Change Processor State, Disable Interrupts | - |
| CPSIE | i | Change Processor State, Enable Interrupts | - |
| DMB | - | Data Memory Barrier | - |
| DSB | - | Data Synchronization Barrier | - |
| EORS | {Rd,} Rn, Rm | Exclusive OR | N,Z |
| ISB | - | Instruction Synchronization Barrier | - |

| WFI | - | Wait for Interrupt | - |

2.4.1 Intrinsic Functions

ISO/IEC C code cannot directly access some Cortex-M0 instructions. The intrinsic functions that can generate these instructions, provided by the CMSIS and might be provided by a C compiler are described in [Section 2.2.7](#).

2.5 Exception Model

This section describes the exception model. It describes:

- Exception states ([Section 2.5.1](#))
- Exception types ([Section 2.5.2](#))
- Exception handlers ([Section 2.5.3](#))
- Vector table ([Section 2.5.4](#))
- Exception priorities ([Section 2.5.5](#))
- Exception entry and return ([Section 2.5.6](#))

2.5.1 Exception States

Each exception is in one of the following states:

| | |
|---------------------------|--|
| Inactive | The exception is not active and not pending. |
| Pending | The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending. |
| Active | An exception that is being serviced by the processor but has not completed. <i>Note: An exception handler can interrupt the execution of another exception handler. In this case both exceptions are in the active state.</i> |
| Active and pending | The exception is being serviced by the processor and there is a pending exception from the same source. |

2.5.2 Exception Types

The exception types are described in [Table 2-8](#).

Table 2-8 Exception types

| Exception Types | Descriptions |
|------------------------|--|
| Reset | Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts in Thread mode. |
| HardFault | A HardFault is an exception that occurs because of an error during normal or exception processing. HardFaults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority. |
| SVCall | A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers. |
| PendSV | PendSV is an interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. |
| SysTick | A SysTick exception is an exception the system timer generates when it reaches zero. Software can also generate a SysTick exception. In an OS environment, the processor can use this exception as system tick. |
| Interrupt (IRQ) | A interrupt, or IRQ, is an exception signalled by a peripheral, or generated by a software request. All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. |

Table 2-9 Properties of the different exception types

| Exception number ¹⁾ | IRQ number ¹⁾ | Exception type | Priority | Vector address or offset ²⁾ | Activation |
|--------------------------------|--------------------------|----------------|-----------------|--|--------------|
| 1 | - | Reset | -3, the highest | 0x00000004 | Asynchronous |
| 2 | - | Reserved | - | - | - |
| 3 | -13 | HardFault | -1 | 0x0000000C | Synchronous |

Central Processing Unit (CPU)

Table 2-9 Properties of the different exception types (cont'd)

| Exception number ¹⁾ | IRQ number ¹⁾ | Exception type | Priority | Vector address or offset ²⁾ | Activation |
|--------------------------------|--------------------------|-----------------|----------------------------|--|--------------|
| 4-10 | - | Reserved | - | - | - |
| 11 | -5 | SVCALL | Configurable ³⁾ | 0x0000002C | Synchronous |
| 12-13 | - | Reserved | - | - | - |
| 14 | -2 | PendSV | Configurable ³⁾ | 0x00000038 | Asynchronous |
| 15 | -1 | SysTick | Configurable ³⁾ | 0x0000003C | Asynchronous |
| 16 and above | 0 and above | Interrupt (IRQ) | Configurable ³⁾ | 0x00000040 and above ⁴⁾ | Asynchronous |

1) To simplify the software layer, the CMSIS only uses IRQ numbers and therefore uses negative values for exceptions other than interrupts. The IPSR returns the Exception number, see [Interrupt Program Status Register](#).

2) See Vector table in [Section 2.5.4](#) for more information.

3) See Interrupt Priority Registers in Interrupt System chapter.

4) Increasing in steps of 4.

For an asynchronous exception, other than reset, the processor can execute additional instructions between when the exception is triggered and when the processor enters the exception handler.

Software can disable the exceptions in [Table 2-9](#) which have configurable priority, see Interrupt Clear-enable Register in Interrupt System chapter.

For more information about HardFaults, see Fault handling in [Section 2.6](#).

2.5.3 Exception Handlers

The processor handles exceptions using:

Interrupt Service Routines (ISRs) Interrupts IRQ0 to IRQ31 are the exceptions handled by ISRs.

Fault handlers HardFault is the only exception handled by the fault handler.

System handlers PendSV, SVCALL, SysTick, and the HardFault are all system exceptions that are handled by system handlers.

2.5.4 Vector Table

The vector table contains the reset value of the stack pointer, and the start addresses, also called exception vectors, for all exception handlers. [Figure 2-6](#) shows the order of

Central Processing Unit (CPU)

the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is written in Thumb code.

| Exception number | IRQ number | Offset | Vector |
|------------------|------------|--------|------------------|
| 47 | 31 | 0x00BC | IRQ31 |
| . | | . | . |
| . | | . | . |
| . | | . | . |
| 18 | 2 | 0x0048 | IRQ2 |
| 17 | 1 | 0x0044 | IRQ1 |
| 16 | 0 | 0x0040 | IRQ0 |
| 15 | -1 | 0x003C | Systick |
| 14 | -2 | 0x0038 | PendSV |
| 13 | | | Reserved |
| 12 | | | |
| 11 | -5 | 0x002C | SVCall |
| 10 | | | |
| 9 | | | |
| 8 | | | |
| 7 | | | Reserved |
| 6 | | | |
| 5 | | | |
| 4 | | | |
| 3 | -13 | 0x0010 | Hard fault |
| 2 | | 0x000C | Reserved |
| 1 | | | Reset |
| | | 0x0004 | Initial SP value |
| | | 0x0000 | |

Figure 2-6 Vector table

The vector table is fixed at address 0x00000000.

2.5.4.1 Vector Table Remap

In XMC1100, the vector table is located inside the ROM. Therefore, the vector table is remapped to the SRAM based on the mapping shown in [Table 2-10](#). The user application uses these locations as entry points for the actual exception and interrupt handlers. This is done by placing the code for these handlers or having the branch instruction to the handlers there.

Central Processing Unit (CPU)

For example, upon an exception entry due to IRQ0, the processor reads the intermediate handler start address 2000'0040_H (fixed in ROM) from the vector table and starts execution from there. If the actual handler is located in another address location due to size constraints, the address 2000'0040_H should trigger a load and a branch instruction to jump to this new location.

Note: The user application needs to reserve the SRAM addresses 2000'000C_H - 2000'00BF_H for the remapped vector table if all vectors are used.

Table 2-10 Remapped Vector Table

| Exception Number | IRQ Number | Vector | Default Vector Address | Remapped Vector Address |
|------------------|------------|------------------|--------------------------------|--------------------------------------|
| - | - | Initial SP Value | 0000'0000 _H | 1000'1000 _H |
| 1 | - | Reset | 0000'0004 _H | 1000'1004 _H ¹⁾ |
| 3 | -13 | HardFault | 0000'000C _H | 2000'000C _H |
| 11 | -5 | SVCall | 0000'002C _H | 2000'002C _H |
| 14 | -2 | PendSV | 0000'0038 _H | 2000'0038 _H |
| 15 | -1 | SysTick | 0000'003C _H | 2000'003C _H |
| 16-47 | 0-31 | IRQn (n=0-31) | 0000'0040 _H + (n*4) | 2000'0040 _H + (n*4) |

1) The remapped reset vector address refers to the location (start of the Flash memory) that the startup software jumps to upon exiting the startup sequence in user mode.

2.5.5 Exception Priorities

Table 2-9 shows that all exceptions have an associated priority, with:

- a lower priority value indicating a higher priority
- configurable priorities for all exceptions except Reset and HardFault.

If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities see

- System Handler Priority Registers [SHPR2](#), [SHPR3](#).
- Interrupt Priority Registers in Interrupt System chapter.

Note: Configurable priority values are in the range 0-192, in steps of 64. This means that the Reset and HardFault exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

Central Processing Unit (CPU)

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

2.5.6 Exception Entry and Return

Exception handling can be described using the following terms:

Preemption

When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. When one exception preempts another, the exceptions are called nested exceptions. See Exception entry in [Section 2.5.6.1](#) for more information.

Source of figure [\[4\]](#).

Return

This occurs when the exception handler is completed, and:

- there is no pending exception with sufficient priority to be serviced
- the completed exception handler was not handling a late-arriving exception.

The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See Exception return in [Section 2.5.6.2](#) for more information.

Tail-chaining

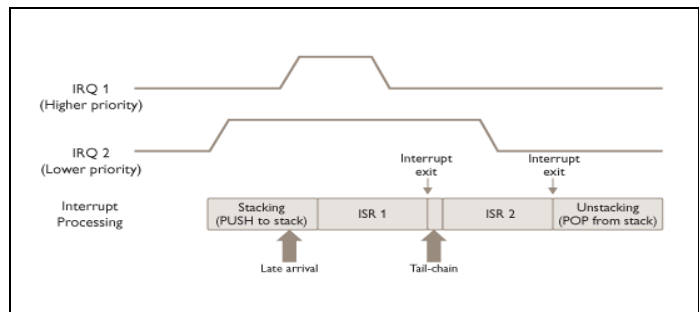

This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.

Source of figure [4].

Late-arriving

This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. On return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

Source of figure [4].

2.5.6.1 Exception entry

Exception entry occurs when there is a pending exception with sufficient priority and either:

Central Processing Unit (CPU)

- the processor is in Thread mode
- the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has greater priority than any limits set by the mask register, see [Exception mask registers](#). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as stacking and the structure of eight data words is referred to as a stack frame. The stack frame contains the following information, as illustrated in [Figure 2-7](#).

Figure 2-7 Exception stack frame

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame. The stack frame is aligned to a double-word address.

The stack frame includes the return address. This is the address of the next instruction in the interrupted program. This value is restored to the PC at exception return so that the interrupted program resumes.

The processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an EXC_RETURN value to the LR. This indicates which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

Central Processing Unit (CPU)

If another higher priority exception occurs during exception entry, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception. This is the late arrival case.

2.5.6.2 Exception return

Exception return occurs when the processor is in Handler mode and execution of one of the following instructions attempts to set the PC to an EXC_RETURN value:

- a POP instruction that loads the PC
- a BX instruction using any register.

The processor saves an EXC_RETURN value to the LR on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. Bits [31:4] of an EXC_RETURN value are set to 1. When this value is loaded into the PC, the processor detects that the exception is complete, and starts the exception return sequence. Bits [3:0] of the EXC_RETURN value indicate the required return stack and processor mode. [Table 2-11](#) shows the EXC_RETURN values with description of the exception return behavior.

Table 2-11 Exception return behavior

| EXC_RETURN[31:0] | Description |
|-------------------------|---|
| 0xFFFFFFF1 | Return to Handler mode. Exception return gets state from the main stack. Execution uses MSP after return. |
| 0xFFFFFFF9 | Return to Thread mode. Exception return gets state from MSP. Execution uses MSP after return. |
| 0xFFFFFFF1D | Return to Thread mode. Exception return gets state from the PSP. Execution uses PSP after return. |
| All other values | Reserved. |

2.6 Fault Handling

Faults are a subset of the exceptions, see Exception model in [Section 2.5](#). All faults result in the HardFault exception being taken or cause lockup if they occur in the HardFault handler. The faults are:

- execution of an SVC instruction at a priority equal or higher than SVCall
- execution of a BKPT instruction without a debugger attached
- a system-generated bus error on a load or store
- execution of an instruction from an XN memory address
- execution of an instruction from a location for which the system generates a bus fault
- a system-generated bus error on a vector fetch
- execution of an undefined instruction
- execution of an instruction when not in Thumb-State as a result of the T-bit being previously cleared to 0
- an attempted load or store to an unaligned address

Note: Only Reset can preempt the fixed priority HardFault handler. A HardFault can preempt any exception other than Reset, or another hard fault.

2.6.1 Lockup

The processor enters a lockup state if a fault occurs when executing the HardFault handlers, or if the system generates a bus error when unstacking the PSR on an exception return using the MSP. When the processor is in lockup state it does not execute any instructions. The processor remains in lockup state until one of the following occurs:

- it is reset
- it is halted by a debugger

2.7 Power Management

The Cortex-M0 processor sleep modes reduce power consumption:

- Sleep mode
- Deep sleep mode

The SLEEPDEEP bit of the SCR selects which sleep mode is used, see System Control Register [SCR](#).

This section describes the mechanisms for entering sleep mode, and the conditions for waking up from sleep mode.

2.7.1 Entering Sleep Mode

This section describes the mechanisms software can use to put the processor into sleep mode.

The system can generate spurious wakeup events, for example a debug operation wakes up the processor. Therefore software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

Wait for interrupt

The wait for interrupt instruction, WFI, causes immediate entry to sleep mode. When the processor executes a WFI instruction it stops executing instructions and enters sleep mode.

Wait for event

The wait for event instruction, WFE, causes entry to sleep mode depending on the value of a one-bit event register. When the processor executes a WFE instruction, it checks the value of the event register:

- 0 The processor stops executing instructions and enters sleep mode.
- 1 The processor clears the register to 0 and continues executing instructions without entering sleep mode.

If the event register is 1, this indicates that the processor must not enter sleep mode on execution of a WFE instruction. Typically, this is because an external event is asserted. Software cannot access this register directly.

Sleep-on-exit

If the SLEEPONEXIT bit of the SCR is set to 1, when the processor completes the execution of an exception handler and returns to Thread mode, it immediately enters sleep mode. This mechanism is used in applications that only require the processor to run when an interrupt occurs.

2.7.2 Wakeup from Sleep Mode

The conditions for the processor to wakeup depend on the mechanism that caused it to enter sleep mode.

Wakeup from WFI or Sleep-on-exit

The following events are WFI wake-up events:

- reset event
- debug event, if debug is enabled
- exception at a priority that would preempt any currently active exceptions, if PRIMASK was set to 0

Note: If PRIMASK is set to 1, an interrupt or exception that has a higher priority than the current exception priority will cause the processor to wake up. Interrupt handler is not executed until the processor sets PRIMASK to 0. For more information about PRIMASK, see [Exception mask registers](#).

Wakeup from WFE

The following events are WFE wake-up events:

- reset event
- exception or interrupt with sufficient priority to cause exception entry
- exception or interrupt entering pending state, if SEVONPEND is set to 1 (See [SCR](#))
- debug event, if debug is enabled

Note: Wakeup by Event Register (see [The Event Register in ARMv6-M Architecture Reference Manual \[2\]](#)) is not possible in XMC1100. Nevertheless, SEV instruction will set the event register.

2.7.3 Power Management Programming Hints

ISO/IEC C cannot directly generate the WFI and WFE instructions. The CMSIS provides the following functions for these instructions:

```
void __WFE(void) // Wait for Event  
void __WFI(void) // Wait for Interrupt
```

2.8 Private Peripherals

The following sections are the reference material for the ARM Cortex-M0 core peripherals.

2.8.1 About the Private Peripherals

The address map of the Private Peripheral Bus (PPB) is:

Table 2-12 Core peripheral register regions

| Address | Core peripheral | Description |
|-----------------------|--------------------------------------|---|
| 0xE000E008-0xE000E00F | System Control Block | See Section 2.8.2 and Section 2.9.1 |
| 0xE000E010-0xE000E01F | System timer | See Section 2.8.3 and Section 2.9.2 |
| 0xE000E100-0xE000E4EF | Nested Vectored Interrupt Controller | See Interrupt System chapter |
| 0xE000ED00-0xE000ED3F | System Control Block | See Section 2.8.2 and Section 2.9.1 |
| 0xE000EF00-0xE000EF03 | Nested Vectored Interrupt Controller | See Interrupt System chapter |

2.8.2 System control block

The System Control Block (SCB) provides system implementation information, and system control. This includes configuration, control, and reporting of the system exceptions.

2.8.2.1 System control block usage hints and tips

Ensure software uses aligned 32-bit word size transactions to access all the system control block registers.

2.8.3 System timer, SysTick

The processor has a 24-bit system timer, SysTick, that counts down from the reload value to zero, reloads, that is wraps to, the value in the SYST_RVR register on the next clock cycle, then counts down on subsequent clock cycles.

Note: When the processor is halted for debugging the counter does not decrement.

2.8.3.1 SysTick usage hints and tips

The interrupt controller clock updates the SysTick count. When processor clock is selected and the clock signal is stopped for low power mode, the SysTick counter stops. When external clock is selected, the clock continues to run in low power mode and SysTick can be used as a wakeup source.

Ensure software uses aligned word accesses to access the SysTick registers.

If the SysTick counter reload and current value are undefined at reset, the correct initialization sequence for the SysTick counter is:

1. Program reload value.
2. Clear current value.
3. Program Control and Status register.

Central Processing Unit (CPU)

2.9 PPB Registers

The CPU private peripherals registers base address is E000E000_H.

Table 2-13 Register Overview

| Short Name | Description | Offset Address | Access Mode | | Description See |
|----------------------------|--|------------------|-------------|--------|---------------------------|

2.9.1 SCS Registers

CPUID

The CPUID register contains the processor part number, version, and implementation information.

CPUID

CPUID Base Register (E000ED00_H) **Reset Value: 410CC200_H**

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| Revision | [3:0] | r | Revision Number 0 _H Patch 0 |
| PartNo | [15:4] | r | Part Number of the Processor C20 _H Cortex-M0 |
| Architecture | [19:16] | r | Architecture C _H ARMv6-M |
| Variant | [23:20] | r | Variant Number 0 _H Revision 0 |
| Implementer | [31:24] | r | Implementer Code 41 _H ARM |

Central Processing Unit (CPU)

ICSR

The ICSR:

- provides:
 - set-pending and clear-pending bits for the PendSV and SysTick exceptions
- indicates:
 - the exception number of the exception being processed
 - whether there are preempted active exceptions
 - the exception number of the highest priority pending exception
 - whether any interrupts are pending.

ICSR

Interrupt Control and State Register

(E000ED04_H)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|-------------|----|----|-------------------|-------------------|-------------------|-------------------|----|----|--------------------|------------|----|----|-----------------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | PEN DSV SET | PEN DSV CLR | PEN DST SET | PEN DST CLR | 0 | | ISRP ENDI NG | 0 | | | VECTPEN DING | | |

| VECTPENDING | | | | 0 | | | | | | VECTACTIVE | | | | | |
| r | | | | r | | | | | | r | | | | | |

| Field | Bits | Type | Description |
|--------------------------|--------|------|---|
| VECTACTIVE ¹⁾ | [5:0] | r | Active Exception Number 00 _H Thread mode Non-zero value The exception number of the currently active exception. <i>Note: Subtract 16 from this value to obtain the CMSIS IRQ number required to index into the Interrupt Clear-Enable, Set-Enable, Clear-Pending, Set-Pending, or Priority Registers, see Interrupt Program Status Register.</i> |
| 0 | [11:6] | r | Reserved Read as 0; should be written with 0. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|--------------------|---------|------|---|
| VECTPENDING | [17:12] | r | Pending Exception Number Indicates the exception number of the highest priority pending enabled exception. 0 _H No pending exceptions Non-zero value: The exception number of the highest priority pending enabled exception. |
| 0 | [21:18] | r | Reserved Read as 0; should be written with 0. |
| ISRPENDING | 22 | r | Interrupt Pending Flag This bit sets the interrupt pending flag, excluding faults. 0 _B Interrupt not pending 1 _B Interrupt pending. |
| 0 | [24:23] | r | Reserved Read as 0; should be written with 0. |
| PENDSTCLR | 25 | w | SysTick Exception Clear-pending 0 _B No effect 1 _B removes the pending state from the SysTick exception. This bit is write-only. On a register read, this value is unknown. |
| PENDSTSET | 26 | rw | SysTick Exception Set-pending 0 _D SysTick exception is not pending 1 _D SysTick exception is pending. A write of 0 to the bit has no effect. |
| PENDSVCLR | 27 | w | PendSV Clear Pending This bit clears a pending PendSV exception. 0 _B Do not clear. 1 _B Removes pending state from PendSV exception. |
| PENDSVSET | 28 | rw | PendSV Set Pending This bit sets a pending PendSV exception or reads back the current state. 0 _B PendSV exception is not pending. 1 _B PendSV exception is pending. <i>Note: Writing 1 to this bit is the only way to set the PendSV exception state to pending.</i> A software write of 0 to the bit has no effect. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|----------|---------|------|---|
| 0 | [31:29] | r | Reserved Read as 0; should be written with 0. |

1) This is the same value as IPSR bits[5:0], see [Interrupt Program Status Register](#).

Note: The result is unpredictable if:

1. Both *PENDSVSET* and *PENDSVCLR* bits are set to 1.
2. Both *PENDSTSET* and *PENDSTCLR* bits are set to 1.

Central Processing Unit (CPU)

AIRCR

The AIRCR register provides endian status for data accesses and reset control of the system. To write to this register, you must write 0x5FA to the VECTKEY field, otherwise the processor ignores the write.

AIRCR

Application Interrupt and Reset Control Register
(E000ED0C_H)

Reset Value: FA050000_H

| Field | Bits | Type | Description |
|--------------------|---------|------|---|
| 0 | 0 | r | Reserved Read as 0; should be written with 0. |
| 0 | 1 | w | Reserved Must be written with 0. |
| SYSRESETREQ | 2 | w | System Reset Request 0 _B No effect. 1 _B Requests a system level reset. This bit is read as 0. |
| 0 | [14:3] | r | Reserved Read as 0; should be written with 0. |
| ENDIANNESS | 15 | r | Data Endianness 0 _B Little-endian |
| VECTKEY | [31:16] | rw | Register Key Reads as unknown. On writes, write 0x5FA to VECTKEY, otherwise the write is ignored. |

Central Processing Unit (CPU)

SCR

The SCR controls features of entry to and exit from low power state.

SCR

System Control Register

(E000ED10_H)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|-------------------|----|-------------------|-------------------------|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | | | | SEV ONP END | 0 | SLE EPD EEP | SLE EPO NEXI T | 0 |
| r | | | | | | | | | | | rw | r | rw | rw | r |

| Field | Bits | Type | Description |
|--------------------|------|------|---|
| 0 | 0 | r | Reserved Read as 0; should be written with 0. |
| SLEEPONEXIT | 1 | rw | Sleep-on-exit This bit indicates sleep-on-exit when returning from Handler mode to Thread mode. 0 _B Do not sleep when returning to Thread mode. 1 _B Enter sleep, or deep sleep, on return from an ISR to Thread mode. Setting this bit to 1 enables an interrupt driven application to avoid returning to an empty main application. |
| SLEEPDEEP | 2 | rw | Low Power Sleep Mode This bit controls whether the processor uses sleep or deep sleep as its low power mode. 0 _B Sleep 1 _B Deep sleep |
| 0 | 3 | r | Reserved Read as 0; should be written with 0. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| SEVONPEND | 4 | rw | Send Event on Pending bit 0_B Only enabled interrupts or events can wakeup the processor, disabled interrupts are excluded. 1_B Enabled events and all interrupts, including disabled interrupts, can wakeup the processor. When an event or interrupt enters pending state, the event signal wakes up the processor from WFE. If the processor is not waiting for an event, the event is registered and affects the next WFE. |
| 0 | [31:5] | r | Reserved Read as 0; should be written with 0. |

Central Processing Unit (CPU)

CCR

The CCR is a read-only register and it indicates some aspects of the behavior of the Cortex-M0 processor.

CCR

Configuration and Control Register

(E000ED14_H)

Reset Value: 00000208_H

| Field | Bits | Type | Description |
|--------------------|---------|------|---|
| 0 | [2:0] | r | Reserved Read as 0; should be written with 0. |
| UNALIGN_TRP | 3 | r | Unaligned Access Traps This bit always reads as 1, indicates that all unaligned accesses generate a HardFault. |
| 0 | [8:4] | r | Reserved Read as 0; should be written with 0. |
| STKALIGN | 9 | r | Stack Alignment This bit always reads as 1, indicates 8-byte stack alignment on exception entry. On exception entry, the processor uses bit [9] of the stacked PSR to indicate the stack alignment. On return from the exception, it uses this stacked bit to restore the correct stack alignment. |
| 0 | [31:10] | r | Reserved Read as 0; should be written with 0. |

System Handler Priority Registers

The SHPR2-SHPR3 registers set the priority level, 0 to 192, of the exception handlers that have configurable priority.

SHPR2-SHPR3 are word accessible. To access to the system exception priority level using CMSIS, the following CMSIS functions are used:

- `uint32_t NVIC_GetPriority(IRQn_Type IRQn)`
- `void NVIC_SetPriority(IRQn_Type IRQn, uint32_t priority)`

The system fault handlers, the priority field and register for each handler are:

Table 2-14 System fault handler priority fields

| Handler | Field | Register description |
|---------|--------|---|
| SVCall | PRI_11 | System Handler Priority Register 2 on Page 2-49 |
| PendSV | PRI_14 | System Handler Priority Register 3 on Page 2-50 |
| SysTick | PRI_15 | |

Each PRI_N field is 8 bits wide, but the XMC1100 implements only bits [7:6] of each field, and bits [5:0] read as zero and ignore writes.

SHPR2

The SHPR2 register sets the priority level for the SVCAll handler.

SHPR2

System Handler Priority Register 2

(E000ED1C_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| 0 | [23:0] | r | Reserved Read as 0; should be written with 0. |
| PRI_11 | [31:24] | rw | Priority of System Handler 11 SVCall. |

SHPR3

The SHPR3 register sets the priority level for the PendSV and SysTick handlers.

SHPR3

System Handler Priority Register 3

(E000ED20_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| 0 | [15:0] | r | Reserved Read as 0; should be written with 0. |
| PRI_14 | [23:16] | rw | Priority of System Handler 14 PendSV. |
| PRI_15 | [31:24] | rw | Priority of System Handler 15 SysTick exception. |

Central Processing Unit (CPU)

SHCSR

The SHCSR register controls and provides the status of system handlers.

SHCSR

System Handler Control and State Register

(E000ED24_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|--------------------------|---------|------|---|
| 0 | [14:0] | r | Reserved Read as 0; should be written with 0. |
| SVCALLPENDE D | 15 | rw | SVCAll Pending bit This bit reflects the pending state on a read, and updates the pending state, to the value written, on a write. 0 _B SVCAll is not pending. 1 _B SVCAll is pending ¹⁾ . |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

1) Pending state bits are set to 1 when an exception occurs, and are cleared to 0 when an exception becomes active.

2.9.2 SysTick Registers

SYST_CSR

The SYST_CSR register enables the SysTick features.

Reading SYST_CSR clears the COUNTFLAG bit to 0.

SYST_CSR

SysTick Control and Status Register

(E000E010_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-----------|------|------|--|
| ENABLE | 0 | rw | Counter Enable This bit enables the counter. 0 _B Counter disabled. 1 _B Counter enabled. |
| TICKINT | 1 | rw | SysTick Exception Request This bit enables the SysTick exception request. 0 _B Counting down to zero does not assert the SysTick exception request. 1 _B Counting down to zero to assert the SysTick exception request. In software, COUNTFLAG bit can be used to determine if SysTick has counted to zero. |
| CLKSOURCE | 2 | rw | Clock Source This bit selects the SysTick timer clock source. 0 _B External clock ¹⁾ . 1 _B Processor clock. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|------------------|---------|------|---|
| 0 | [15:3] | r | Reserved Read as 0; should be written with 0. |
| COUNTFLAG | 16 | rw | Counter Flag This bit returns 1 if timer counted to 0 since the last read of this register. |
| 0 | [31:17] | r | Reserved Read as 0; should be written with 0. |

1) In XMC1100, the external clock refers to the on-chip 32 kHz standby clock.

When ENABLE is set to 1, the counter loads the RELOAD value from the SYST_RVR register and then counts down. On reaching 0, it sets the COUNTFLAG to 1 and optionally asserts the SysTick depending on the value of TICKINT. It then loads the RELOAD value again, and begins counting.

SYST_RVR

The SYST_RVR register specifies the start value to load into the SYST_CVR register.

SYST_RVR

SysTick Reload Value Register (E000E014_H) **Reset Value: XXXXXXXX_H**

| Field | Bits | Type | Description |
|--------|---------|------|--|
| RELOAD | [23:0] | rw | Reload Value This field sets the value to load into the SYST_CVR register when the counter is enabled and when it reaches 0. |
| 0 | [31:24] | r | Reserved Read as 0; should be written with 0. |

Notes on calculating the RELOAD value

1. The RELOAD value can be any value in the range 0x00000001-0x00FFFFFF. A start value of 0 is possible, but this has no effect because the SysTick exception request and COUNTFLAG are activated when counting from 1 to 0.
2. The RELOAD value is calculated according to its use. For example, to generate a multi-shot timer with a period of N processor clock cycles, use a RELOAD value of N-1. If the SysTick interrupt is required every 100 clock pulses, set RELOAD to 99.

SYST_CVR

The SYST_CVR register contains the current value of the SysTick counter.

Writing to the SYST_CVR clears the register and the COUNTFLAG status bit to 0. The write does not trigger the SysTick exception logic. Reading the register returns its value at the time it is accessed.

SYST_CVR

SysTick Current Value Register (E000E018_H) **Reset Value: XXXXXXXX_H**

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| CURRENT | [23:0] | rw | SysTick Counter Current Value When read, it returns the current value of the SysTick counter. A write of any value clears the field to 0, and also clears the SYST_CSR.COUNTFLAG bit to 0. |
| 0 | [31:24] | r | Reserved Read as 0; should be written with 0. |

SYST_CALIB

The SYST_CALIB register indicates the SysTick calibration properties.

SYST_CALIB

SysTick Calibration Value Register(E000E01C_H)

Reset Value: 40000147_H

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| TENMS | [23:0] | r | 10 Milliseconds The reload value for 10ms timing is subject to system clock skew errors. The default value of TENMS is 0x000147. |
| 0 | [29:24] | r | Reserved Read as 0; should be written with 0. |
| SKEW | 30 | r | Clock Skew This bit is read as 1. It indicates that 10ms calibration value is inexact, because of the clock frequency. |
| NOREF | 31 | r | Reference Clock This bit is read as 0. It indicates that external reference clock is provided. |

3 Bus System

The single master bus system in XMC1100 consists of a high-performance system bus based on the industry AMBA 3 AHB-Lite Protocol standard for memories and high-bandwidth on-chip peripherals and a narrower APB for low-bandwidth on-chip peripherals.

3.1 Bus Interfaces

This chapter describes the features for the two kinds of interfaces.

- Memory Interface
- Peripheral Interface

All on-chip modules implement Little Endian data organization.

Memory Interface

The on-chip memories are capable to accept a transfer request with each bus clock cycle.

The memory interface data bus width is 32-bit. Flash memory supports only 32-bit accesses while SRAM allows 32-bit, 16-bit and 8-bit write accesses. Read accesses to SRAM is always 32-bit wide.

Peripheral Interface

Each slave on the AHB-Lite supports 32-bit accesses. Additionally:

- USIC0 supports 8-bit and 16-bit accesses

Each slave on the APB supports only 16-bit accesses.

Note: Unaligned memory accesses to memory or peripheral slaves result in a HardFault exception.

4 Service Request Processing

A hardware pulse is called Service Request (SR) in an XMC1100 system. Service Requests are the fastest way to send trigger “messages” between connected on-chip resources.

An SR can generate any of the following requests

- Interrupt
- Peripheral action

This chapter describes the available Service Requests and the different ways to select and process them.

Table 4-1 Abbreviations

| | |
|------|--------------------------------------|
| ERU | Event Request Unit |
| NVIC | Nested Vectored Interrupt Controller |
| SR | Service Request |

4.1 Overview

Efficient Service Request Processing is based on the interconnect between the request sources and the request processing units. XMC1100 provides both fixed and programmable interconnect.

4.1.1 Features

The following features are provided for Service Request processing:

- Connectivity matrix between Service Requests and request processing units
 - Fixed connections
 - Programmable connections using ERU

4.1.2 Block Diagram

Figure 4-1 shows a representation of the interaction between the request sources and the request processing units.

Figure 4-1 Block Diagram on Service Request Processing

4.2 Service Request Distribution

Figure 4-2 shows an example of how a service request can be distributed concurrently. To support the concurrent distribution to multiple receivers, the receiving modules are capable to enable/disable incoming requests.

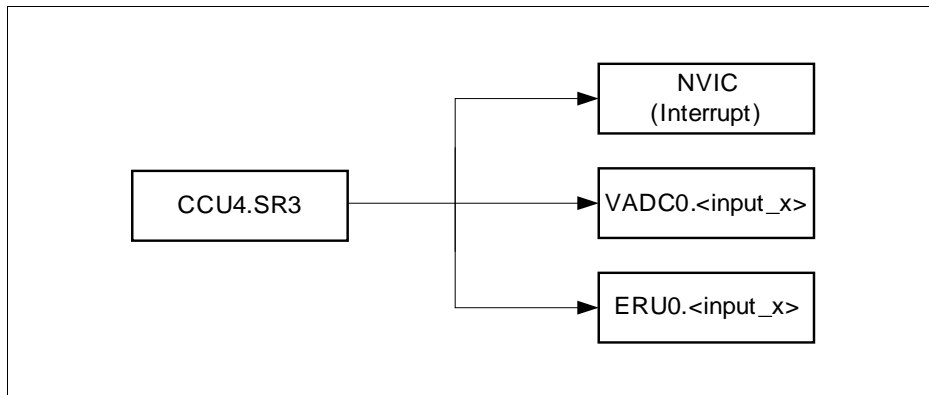

Figure 4-2 Example for Service Request Distribution

The units involved in Service Request distribution can be subdivided into

- Embedded real time services
- Interrupt services

Embedded real time services

Connectivity between On-Chip Units and PORTS is real time application and also chip package dependant. Related connectivity and availability of pins can be looked up in the

- “Interconnects” Section of the respective module(s) chapters
- “Parallel Ports” chapter and Data Sheet for PORTS
- “Event Request Unit” chapter

Interrupt services

The following table gives an overview on the number of service requests per module and how the service requests are assigned to NVIC Interrupt service provider.

Service Requests are always of type “Pulse” in XMC1100.

Table 4-2 Interrupt services per module

| Modules | Request Sources | NVIC | Type |
|----------------|------------------------|-------------|-------------|
| VADC | 4 | 2 | Pulse |
| CCU40 | 4 | 4 | Pulse |
| USIC0 | 6 | 6 | Pulse |
| SCU | 2 | 2 | Pulse |
| ERU0 | 4 | 4 | Pulse |

5 Interrupt Subsystem

The interrupt Subsystem in XMC1100 consists of the Nested Vectored Interrupt Controller (NVIC) and the respective modules' interrupt generation blocks.

Note: The CPU exception model is described in the CPU chapter.

5.1 Nested Vectored Interrupt Controller (NVIC)

The NVIC is an integral part of the Cortex M0 processor unit. Due to a tight coupling with the CPU, it provides the lowest interrupt latency and efficient processing of late arriving interrupts.

5.1.1 Features

The NVIC supports the following features:

- 32 interrupt nodes
- 4 programmable priority levels for each interrupt node
- Support for interrupt tail-chaining and late-arrival
- Software interrupt generation

5.1.2 Interrupt Node Assignment

Table 5-1 lists the service request sources per peripheral and their assignment to NVIC interrupt nodes. For calculation of the vector routine address, please refer to the section on Vector Table in the CPU chapter.

Table 5-1 Interrupt Node assignment

| Service Request | Node ID | Description |
|------------------------------|---------|---|
| SCU.SR0 - SCU.SR2 | 0...1 | System Control SR0 is the system critical request SR1 is the common SCU request |
| NC | 2 | Reserved |
| ERU0.SR0 - ERU0.SR3 | 3...6 | External Request Unit 0 |
| NC | 7...8 | Reserved |
| USIC0.SR0 - USIC0.SR5 | 9...14 | Universal Serial Interface Channel (Module 0) |
| VADC0.C0SR0 - VADC0.C0SR1 | 15...16 | Analog to Digital Converter (Common) |
| NC | 17...20 | Reserved |

Table 5-1 Interrupt Node assignment (cont'd)

| Service Request | Node ID | Description |
|--------------------------|---------|-----------------------------------|
| CCU40.SR0 - CCU40.SR3 | 21...24 | Capture Compare Unit 4 (Module 0) |
| NC | 25...31 | Reserved |

5.1.3 Interrupt Signal Generation

In XMC1100, all peripherals support only the generation of pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock (MCLK). To ensure the NVIC detects the interrupt, the peripheral asserts the interrupt signal for at least one MCLK clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt, see [Hardware and software control of interrupts](#).

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead. This provides low latency exception handling.

Hardware and software control of interrupts

The Cortex-M0 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- the NVIC detects that the interrupt signal is active and the interrupt is not active
- the NVIC detects a rising edge on the interrupt signal
- software writes to the corresponding interrupt set-pending register bit, see Interrupt Set-pending Register NVIC_ISPR.

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt. This changes the state of the interrupt from pending to active. Then:
 - The NVIC continues to monitor the interrupt signal, and If this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.
If the interrupt signal is not pulsed while the processor is in the ISR, the state of the interrupt changes to inactive when the processor returns from the ISR.
- Software writes to the corresponding interrupt clear-pending register bit.
 - The state of the interrupt changes to inactive, if the state was pending; or active, if the state was active and pending.

5.1.4 NVIC design hints and tips

An interrupt node can enter pending state even if it is disabled. Disabling an interrupt node only prevents the processor from taking interrupts from that node.

NVIC programming hints

Software uses the CPSIE i and CPSID i instructions to enable and disable interrupts. The CMSIS provides the following intrinsic functions for these instructions:

```
void __disable_irq(void) // Disable Interrupts
void __enable_irq(void) // Enable Interrupts
```

In addition, the CMSIS provides a number of functions for NVIC control, including:

Table 5-2 CMSIS functions for NVIC control

| CMSIS interrupt control function | Description |
|--|------------------------------------|
| void NVIC_EnableIRQ (IRQn_t IRQn) | Enable IRQn |
| void NVIC_DisableIRQ (IRQn_t IRQn) | Disable IRQn |
| uint32_t NVIC_GetPendingIRQ (IRQn_t IRQn) | Return true (1) if IRQn is pending |
| void NVIC_SetPendingIRQ (IRQn_t IRQn) | Set IRQn pending |
| void NVIC_ClearPendingIRQ (IRQn_t IRQn) | Clear IRQn pending status |
| void NVIC_SetPriority (IRQn_t IRQn, uint32_t priority) | Set priority for IRQn |
| uint32_t NVIC_GetPriority (IRQn_t IRQn) | Read priority of IRQn |
| void NVIC_SystemReset (void) | Reset the system |

The input parameter IRQn is the IRQ number. For more information about these functions, please refer to the CMSIS documentation.

5.1.5 Accessing CPU Registers using CMSIS

CMSIS functions enable software portability between different Cortex-M profile processors. To access the NVIC registers when using CMSIS, use the following functions:

Table 5-3 CMSIS access NVIC functions

| CMSIS function | Description |
|---|-------------------------------------|
| void NVIC_EnableIRQ (IRQn_Type IRQn) ¹⁾ | Enables an interrupt or exception. |
| void NVIC_DisableIRQ (IRQn_Type IRQn) ¹⁾ | Disables an interrupt or exception. |

Table 5-3 CMSIS access NVIC functions (cont'd)

| CMSIS function | Description |
|--|---|
| void NVIC_SetPendingIRQ (IRQn_Type IRQn) ¹⁾ | Sets the pending status of interrupt or exception to 1. |
| void NVIC_ClearPendingIRQ (IRQn_Type IRQn) ¹⁾ | Clears the pending status of interrupt or exception to 0. |
| uint32_t NVIC_GetPendingIRQ (IRQn_Type IRQn) ¹⁾ | Reads the pending status of interrupt or exception. This function returns non-zero value if the pending status is set to 1. |
| void NVIC_SetPriority(IRQn_Type IRQn, uint32_t priority) ¹⁾ | Sets the priority of an interrupt or exception with configurable priority level to 1. |
| uint32_t NVIC_GetPriority(IRQn_Type IRQn) ¹⁾ | Reads the priority of an interrupt or exception with configurable priority level. This function return the current priority level. |

1) The input parameter IRQn is the IRQ number.

5.1.6 Interrupt Priority

An interrupt node can be assigned one of four priority levels. The levels are in steps of 64, from 0 to 192, and defined in an 8-bit priority field in the Interrupt Priority Register x (IPRx). A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.

Since there are four priority fields in each IPRx register and each field corresponds to one interrupt node, altogether 8 IPRx registers (IPR0...IPR7) are needed as shown in [Figure 5-1](#).

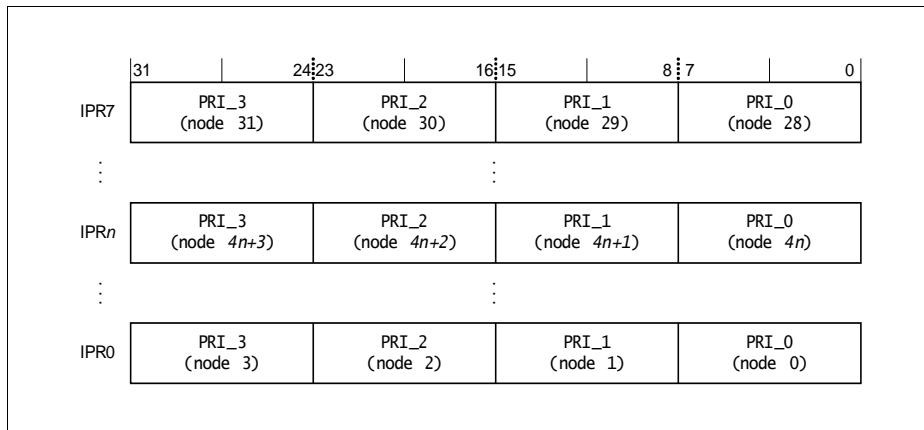

Figure 5-1 Interrupt Priority Register

The IPR number and byte offset for interrupt node m ($0 \dots 31$) can be found as follows:

- the corresponding IPR number n is given by
 $n = m \text{ DIV } 4$
- the byte offset of the required Priority field in this register is $m \text{ MOD } 4$, where:
 - byte offset 0 refers to register bits [7:0]
 - byte offset 1 refers to register bits [15:8]
 - byte offset 2 refers to register bits [23:16]
 - byte offset 3 refers to register bits [31:24]
- for example, Priority field of interrupt node 21 is located at IPR5.[15:8], since
 - $n = 21 \text{ DIV } 4 = 5$
 - byte offset = $21 \text{ MOD } 4 = 1$

Note: IPRx registers are only word-accessible.

Refer to [Table 5-2](#) for more information on the access to the interrupt node priority array, which provides the software view of the interrupt node priorities.

5.1.7 Interrupt Latency

The XMC1100 interrupt latency, defined as the time from detection of the generated pulse and latching of the interrupt by NVIC to execution of the first instruction at the interrupt handler, is typically 21 MCLK cycles as shown in [Figure 5-2](#).

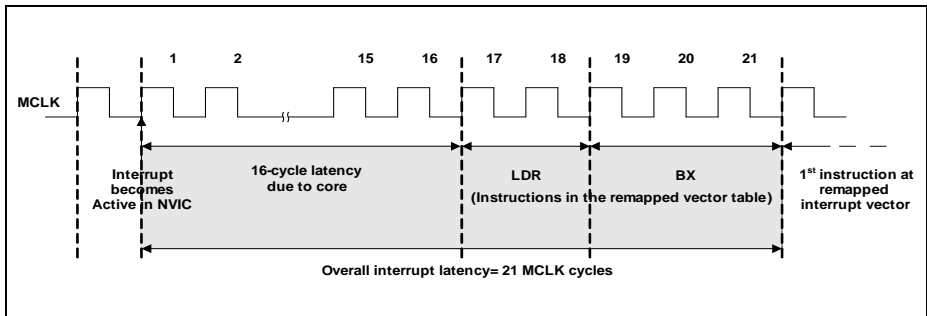

Figure 5-2 Typical XMC1100 Interrupt Latency

This assumes the following conditions:

- Interrupt generation is enabled
- No occurrence of interrupt pre-emption, late-arrival or tail-chaining
- Delays due to memory wait states are not taken into account

5.2 General Module Interrupt Structure

A module might have multiple interrupt sources. Each interrupt source has typically the following structure (see [Figure 5-3](#)):

- An interrupt source status flag
- A set bit to allow software to set the flag to 1
- A clear bit to allow software to reset the flag to 0
- An enable bit to trigger interrupt when the hardware event occurs or status flag set bit is set (i.e. software triggered interrupt)

Note: If a flag set event (due to a peripheral HW event) occurs in the same clock cycle as a flag clear event (due to SW Setting of the Clear bit), the set has higher priority over the clear.

Note: Setting of the status flag by a hardware event or software writing to status flag set bit, is independent of interrupt generation enabled/disabled. Similarly, interrupt generation is independent of the level of the status flag.

Additionally, some modules might have more interrupt sources than interrupt lines. Therefore, they include an interrupt routing management block, which maps the interrupt sources to the interrupt lines.

For further details and exceptions to the above general structure, refer to the respective module chapters. An overview of all XMC1100 interrupt sources is given at the end of the chapter.

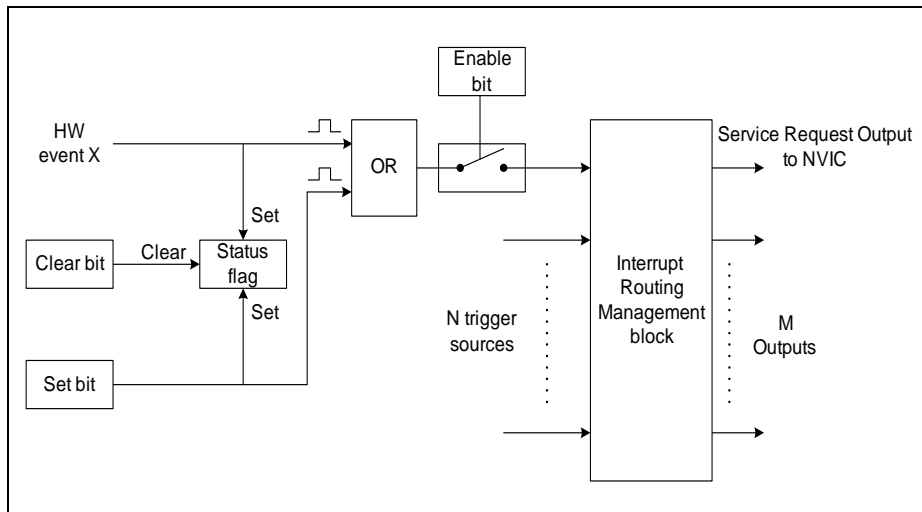

Figure 5-3 Typical Module Interrupt Structure

To enable a module HW event for interrupt generation, SW has to:

- Enable the interrupt node that is allocated to the module in the NVIC, through the NVIC_IUSER register.
- If the module has an interrupt routing management block, select an available service request output through which the interrupt will be generated to the NVIC. This is usually done by configuring an interrupt node pointer register in the module.
- Finally, set the interrupt enable bit of the module HW event for interrupt generation.

5.3 Registers

Table 5-4 Registers Address Space

| Module | Base Address | End Address | Note |
|-------------------------------------|-----------------------|-----------------------|------|
| CPU PPB: System Control Space (SCS) | E000E000 _H | E000EFFF _H | |

Registers Overview

The absolute register address is calculated by adding:
Module Base Address + Offset Address

Table 5-5 Register Overview

| Short Name | Description | Offset Address | Access Mode | | Description See |
|---|-----------------------------------|------------------------------------|-------------|-------|---------------------------|
| | | | Read | Write | |
| Nested Vectored Interrupt Controller (NVIC) | | | | | |
| NVIC_ISER | Interrupt Set-enable Registers | 100 _H | U, PV | U, PV | Page 5-9 |
| NVIC_ICER | Interrupt Clear-enable Registers | 180 _H | U, PV | U, PV | Page 5-10 |
| NVIC_ISPR | Interrupt Set-pending Registers | 200 _H | U, PV | U, PV | Page 5-11 |
| NVIC_ICPR | Interrupt Clear-pending Registers | 280 _H | U, PV | U, PV | Page 5-12 |
| NVIC_IPR0 - NVIC_IPR7 | Interrupt Priority Registers | 400 _H -41C _H | U, PV | U, PV | Page 5-13 |

5.3.1 NVIC Registers

NVIC_ISER

The ISER register enables interrupt nodes, and shows which interrupt nodes are enabled.

NVIC_ISER

Interrupt Set-enable Register (E000E100_H) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|--------|--------|------|--|
| SETENA | [31:0] | rw | Interrupt Node Set-enable 0 _B Read: Interrupt node disabled. Write: No effect. 1 _B Read: Interrupt node enabled. Write: Enable interrupt node |

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

NVIC_ICER

The ICER register disables interrupt nodes, and shows which interrupt nodes are enabled.

NVIC_ICER

Interrupt Clear-enable Register (E000E180_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|--------|--------|------|---|
| CLRENA | [31:0] | rw | Interrupt Node Clear-enable 0 _B Read: Interrupt node disabled. Write: No effect 1 _B Read: Interrupt node enabled. Write: Disable interrupt node. |

NVIC_ISPR

The ISPR register forces interrupt nodes into the pending state, and shows which interrupt nodes are pending.

NVIC_ISPR

Interrupt Set-pending Register

(E000E200_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|---------|--------|------|--|
| SETPEND | [31:0] | rw | Interrupt Node Set-pending 0 _B Read: Interrupt node is not pending. Write: No effect 1 _B Read: Interrupt node is pending. Write: Change interrupt state to pending. |

Note: Writing 1 to the ISPR bit corresponding to:

- *an interrupt node that is pending has no effect*
- *a disabled interrupt node sets the state of that interrupt node to pending*

NVIC_ICPR

The ICPR register removes the pending state from interrupt nodes, and shows which interrupt nodes are pending.

NVIC_ICPR

Interrupt Clear-pending Register

(E000E280_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|----------------|--------|------|---|
| CLRPEND | [31:0] | rw | Interrupt Node Clear-pending 0 _B Read: Interrupt node is not pending. Write: No effect. 1 _B Read: Interrupt node is pending. Write: Remove interrupt state from pending. |

Note: Writing 1 to an ICPR bit does not affect the active state of the corresponding interrupt node.

NVIC_IPRx (x=0-7)

The IPR0-IPR7 registers provide a 8-bit priority field for each interrupt node. Each register holds four priority fields.

Each priority field holds a priority value, 0-192. The lower the value, the greater the priority of the corresponding interrupt node. The processor implements only bits [7:6] of each field, bits [5:0] reads as 0 and ignores writes. This means writing 255 to a priority register saves value 192 to the register.

NVIC_IPRx (x=0-7)

Interrupt Priority Register x

(E000E400_H + 4*x)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|---------|------|-------------------------|
| PRI_3 | [31:24] | rw | Priority, Byte Offset 3 |
| PRI_2 | [23:16] | rw | Priority, Byte Offset 2 |
| PRI_1 | [15:8] | rw | Priority, Byte Offset 1 |
| PRI_0 | [7:0] | rw | Priority, Byte Offset 0 |

5.4 Interrupt Request Source Overview

An overview of all XMC1100 interrupt sources and related register bits are shown in the next few pages.

Table 5-6 Interrupt Source Overview

| IRQ | Interrupt Node | Interrupt Source | Status Flag | | Interrupt Enable | | Set Flag | | Clear Flag | | Node Pointer | |
|-----|----------------|------------------------------------|----------------|-----------|------------------|---------|-----------|----------|--------------|----------|--------------|-----|

1) Flash ECC double bit error has two status flags, each having its own clear bit. It is sufficient to use only one of the status flag and ignore the other.

6 Event Request Unit (ERU)

As described in the Service Request Processing chapter, XMC1100 uses the Event Request Unit (ERU) to support the programmable interconnection for the processing of service requests.

6.1 Features

The ERU supports these features:

- Flexible processing of external and internal service requests
- Programmable for edge and/or level triggering
- Multiple inputs per channel
- Triggers combinable from multiple inputs
- Input and output gating

6.2 Overview

The Event Request Unit (ERU) is a versatile multiple input event detection and processing unit.

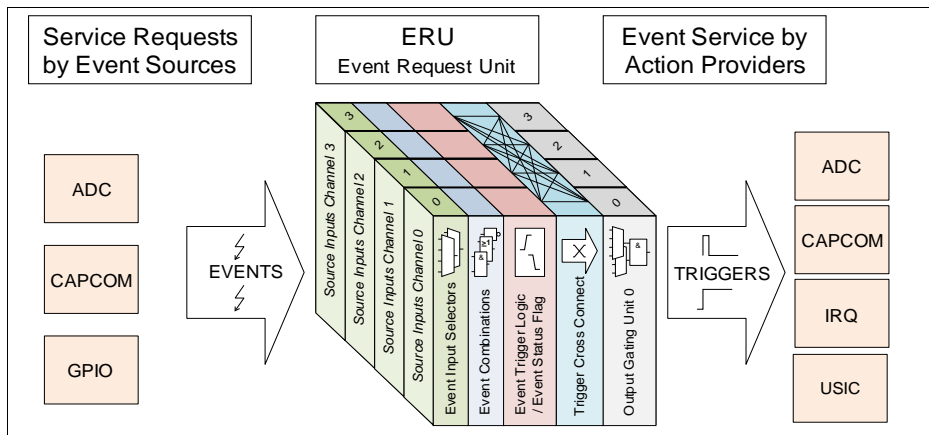

Figure 6-1 Event Request Unit Overview

Each ERU unit consists of the following blocks:

- An **Event Request Select (ERS)** unit.
 - Event Input Selectors allow the selection of one out of two inputs. For each of these two inputs, an vector of 4 possible signals is available.
 - Event Combinations allow a logical combination of two input signals to a common trigger.

Event Request Unit (ERU)

- An **Event Trigger Logic (ETL)** per Input Channel allows the definition of the transition (edge selection, or by software) that lead to a trigger event and can also store this status. Here, the input levels of the selected signals are translated into events.
- The Trigger **Cross Connect Matrix** distributes the events and status flags to the Output Channels. Additionally, trigger signals from other modules are made available and can be combined with the local triggers.
- An **Output Gating Unit (OGU)** combines the trigger events and status information and gates the Output depending on a gating signal.

Note: An event of one Input can lead to reactions on several Outputs, or also events on several Inputs can be combined to a reaction on one Output.

6.3 Event Request Select Unit (ERS)

For each Input Channel x ($x = 0-3$), an ERS x unit handles the input selection for the associated ETL x unit. Each ERS x performs a logical combination of two signals (A_x , B_x) to provide one combined output signal ERS x O to the associated ETL x . Input A_x can be selected from 4 options of the input vector ERU_xA[3:0] and can be optionally inverted. A similar structure exists for input B_x (selection from ERU_xB[3:0]).

In addition to the direct choice of either input A_x or B_x or their inverted values, the possible logical combinations for two selected inputs are a logical AND or a logical OR.

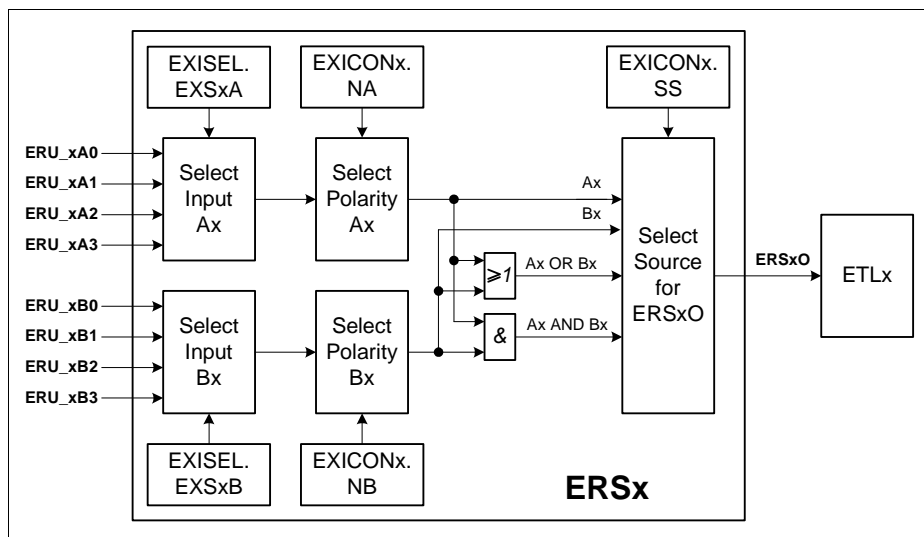

Figure 6-2 Event Request Select Unit Overview

Event Request Unit (ERU)

The ERS units are controlled via register **ERU0_EXISEL** (one register for all four ERSx units) and registers EXICONx (one register for each ERSx and associated ETLx unit, e.g. **ERU0_EXICONx (x=0-3)** for Input Channel 0).

6.4 Event Trigger Logic (ETLx)

For each Input Channel x (x = 0-3), an event trigger logic ETLx derives a trigger event and related status information from the input ERSxO. Each ETLx is based on an edge detection block, where the detection of a rising or a falling edge can be individually enabled. Both edges lead to a trigger event if both enable bits are set (e.g. to handle a toggling input).

Each of the four ETLx units has an associated EXICONx register, that controls all options of an ETLx (the register also holds control bits for the associated ERSx unit, e.g. **ERU0_EXICONx (x=0-3)** to control ERS0 and ETL0).

Figure 6-3 Event Trigger Logic Overview

When the selected event (edge) is detected, the status flag EXICONx.FL becomes set. This flag can also be modified by software. Two different operating modes are supported by this status flag.

It can be used as “sticky” flag, which is set by hardware when the desired event has been detected and has to be cleared by software. In this operating mode, it indicates that the event has taken place, but without indicating the actual status of the input.

Event Request Unit (ERU)

In the second operating mode, it is cleared automatically if the “opposite” event is detected. For example, if only the falling edge detection is enabled to set the status flag, it is cleared when the rising edge is detected. In this mode, it can be used for pattern detection where the actual status of the input is important (enabling both edge detections is not useful in this mode).

The output of the status flag is connected to all following Output Gating Units (OGUy) in parallel (see [Figure 6-4](#)) to provide **pattern detection capability of all OGUy** units based on different or the same status flags.

In addition to the modification of the status flag, a trigger pulse output TRxy of ETLx can be enabled (by bit EXICONx.PE) and selected to **trigger actions in one of the OGUy** units. The target OGUy for the trigger is selected by bit field EXICON.OCS.

The trigger becomes active when the selected edge event is detected, independently from the status flag EXICONx.FL.

6.5 Cross Connect Matrix

The matrix shown in [Figure 6-4](#) distributes the trigger signals (TRxy) and status signals (EXICONx.FL) from the different ETLx units between the OGUy units. In addition, it receives peripheral trigger signals that can be OR-combined with the ETLx trigger signals in the OGUy units.

Event Request Unit (ERU)

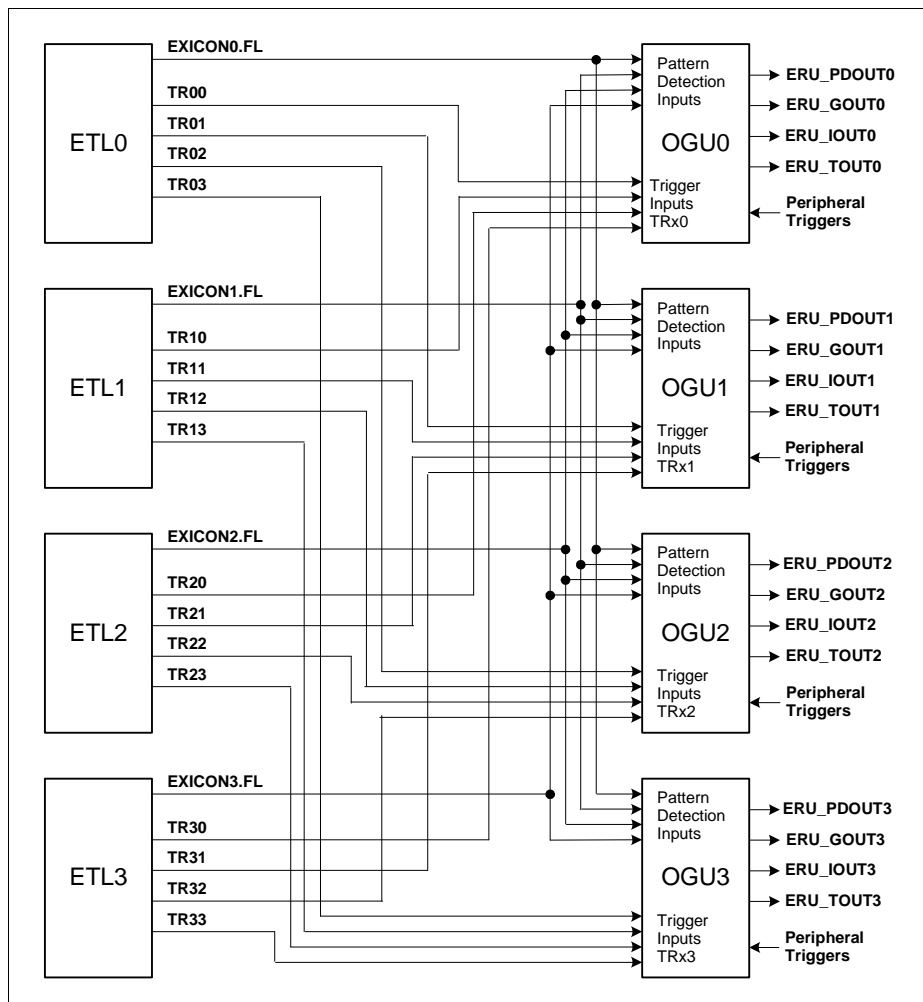

Figure 6-4 ERU Cross Connect Matrix

6.6 Output Gating Unit (OGUy)

Each OGUy (y = 0-3) unit combines the available trigger events and status flags from the Input Channels and distributes the results to the system. [Figure 6-5](#) illustrates the logic blocks within an OGUy unit. All functions of an OGUy unit are controlled by its associated

Event Request Unit (ERU)

EXOCONy register, e.g. **ERU0_EXOCONx (x=0-3)** for OGU0. The function of an OGUy unit can be split into two parts:

- **Trigger Combination:**
All trigger signals TRxy from the Input Channels that are enabled and directed to OGUy, a selected peripheral-related trigger event, and a pattern change event (if enabled) are logically OR-combined.
- **Pattern Detection:**
The status flags EXICONx.FL of the Input Channels can be enabled to take part in the pattern detection. A pattern match is detected while all enabled status flags are set.

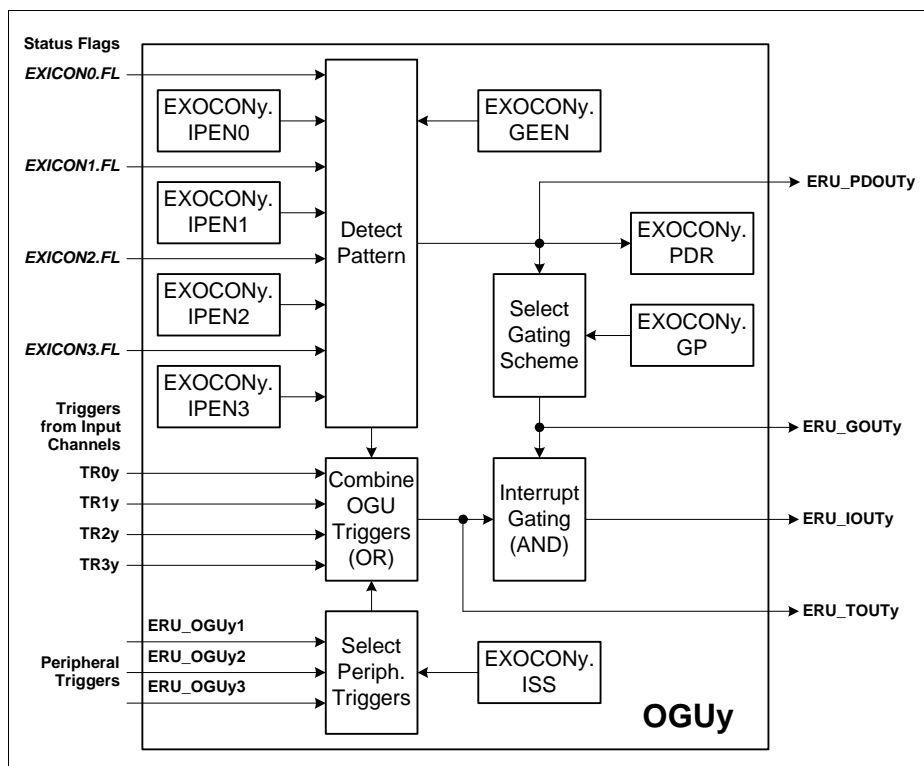

Figure 6-5 Output Gating Unit for Output Channel y

Each OGUy unit generates 4 output signals that are distributed to the system (not all of them are necessarily used):

- **ERU_PDOUTy** to directly output the pattern match information for gating purposes in other modules (pattern match = 1).

Event Request Unit (ERU)

- **ERU_GOUTy** to output the pattern match or pattern miss information (inverted pattern match), or a permanent 0 or 1 under software control for gating purposes in other modules.
- **ERU_TOUTy** as combination of a peripheral trigger, a pattern detection result change event, or the ETLx trigger outputs TRxy to trigger actions in other modules.
- **ERU_IOUTy** as gated trigger output (ERU_GOUTy logical AND-combined with ERU_TOUTy) to trigger service requests (e.g. the service request generation can be gated to allow service request activation during a certain time window).

Trigger Combination

The trigger combination logically OR-combines different trigger inputs to form a common trigger ERU_TOUTy. Possible trigger inputs are:

- In each ETLx unit of the **Input Channels**, the trigger output TRxy can be enabled and the trigger event can be directed to one of the OGUy units.
- One out of three **peripheral trigger** signals per OGUy can be selected as additional trigger source. These peripheral triggers are generated by on-chip peripheral modules, such as capture/compare or timer units. The selection is done by bit field EXOCONy.ISS.
- In the case that at least one **pattern detection** input is enabled (EXOCONy.IPENx) and a change of the pattern detection result from pattern match to pattern miss (or vice-versa) is detected, a trigger event is generated to indicate a pattern detection result event (if enabled by ECOCONy.GEEN).

The trigger combination offers the possibility to program different trigger criteria for several input signals (independently for each Input Channel) or peripheral signals, and to combine their effects to a single output, e.g. to generate an service request or to start an ADC conversion. This combination capability allows the generation of a service request per OGU that can be triggered by several inputs (multitude of request sources results in one reaction).

The selection is defined by the bit fields ISS in registers **ERU0_EXOCONx (x=0-3)**.

Pattern Detection

The pattern detection logic allows the combination of the status flags of all ETLx units. Each status flag can be individually included or excluded from the pattern detection for each OGUy, via control bits EXOCONy.IPENx. The pattern detection block outputs the following pattern detection results:

- **Pattern match** (EXOCONy.PDR = 1 and ERU_PDOUTy = 1):
A pattern match is indicated while all status flags FL that are included in the pattern detection are 1.
- **Pattern miss** (EXOCONy.PDR = 0 and ERU_PDOUTy = 0):
A pattern miss is indicated while at least one of the status flags FL that are included in the pattern detection is 0.

Event Request Unit (ERU)

In addition, the pattern detection can deliver a trigger event if the pattern detection result changes from match to miss or vice-versa (if enabled by EXOCONy.GEEN = 1). The pattern result change event is logically OR-combined with the other enabled trigger events to support service request generation or to trigger other module functions (e.g. in the ADC). The event is indicated when the pattern detection result changes and EXOCONy.PDR becomes updated.

The service request generation in the OGUy is based on the trigger ERU_TOUTy that can be gated (masked) with the pattern detection result ERU_PDOUTy. This allows an automatic and reproducible generation of service requests during a certain time window, where the request event is elaborated by the trigger combination block and the time window information (gating) is given by the pattern detection. For example, service requests can be issued on a regular time base (peripheral trigger input from capture/compare unit is selected) while a combination of input signals occurs (pattern detection based on ETLx status bits).

A programmable gating scheme introduces flexibility to adapt to application requirements and allows the generation of service requests ERU_IOUTy under different conditions:

- **Pattern match** (EXOCONy.GP = 10_B):
A service request is issued when a trigger event occurs while the pattern detection shows a pattern match.
- **Pattern miss** (EXOCONy.GP = 11_B):
A service request is issued when the trigger event occurs while the pattern detection shows a pattern miss.
- **Independent** of pattern detection (EXOCONy.GP = 01_B):
In this mode, each occurring trigger event leads to a service request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy with service requests on trigger events).
- **No service requests** (EXOCONy.GP = 00_B, default setting)
In this mode, an occurring trigger event does not lead to a service request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy without service requests on trigger events).

6.7 Power, Reset and Clock

ERU is running on the main clock, MCLK. It is consuming power in all operating modes as long as the MCLK continues to run.

6.8 Initialization and System Dependencies

Service Requests must always be enabled at the source and at the destination. Additionally it must be checked whether it is necessary to program the ERU0 process and route a request.

Enabling Peripheral SRx Outputs

- Peripherals' SRx outputs must be selectively enabled. This procedure depends on the individual peripheral. Please look up the section "Service Request Generation" within a peripheral chapter for details.
- Optionally ERU0 must be programmed to process and route the request

Enabling External Requests

- Selected PORTS must be programmed for input
- ERU0 must be programmed to process and route the external request

Note: The number of external service request inputs may be limited by the package used.

6.9 Registers

Table 6-1 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| ERU0 | 4001 0600 _H | 4001 06FF _H | |

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Event Request Unit (ERU)

ERU0_EXICONx (x=0-3)

Event Input Control x

(10_H + 4*x)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|------|------|--|
| PE | 0 | rw | Output Trigger Pulse Enable for ETLx This bit enables the generation of an output trigger pulse at TRxy when the selected edge is detected (set condition for the status flag FL). 0 _B The trigger pulse generation is disabled 1 _B The trigger pulse generation is enabled |
| LD | 1 | rw | Rebuild Level Detection for Status Flag for ETLx This bit selects if the status flag FL is used as “sticky” bit or if it rebuilds the result of a level detection. 0 _B The status flag FL is not cleared by hardware and is used as “sticky” bit. Once set, it is not influenced by any edge until it becomes cleared by software. 1 _B The status flag FL rebuilds a level detection of the desired event. It becomes automatically set with a rising edge if RE = 1 or with a falling edge if FE = 1. It becomes automatically cleared with a rising edge if RE = 0 or with a falling edge if FE = 0. |
| RE | 2 | rw | Rising Edge Detection Enable ETLx This bit enables/disables the rising edge event as edge event as set condition for the status flag FL or as possible trigger pulse for TRxy. 0 _B A rising edge is not considered as edge event 1 _B A rising edge is considered as edge event |

Event Request Unit (ERU)

| Field | Bits | Type | Description |
|------------|---------|------|---|
| FE | 3 | rw | Falling Edge Detection Enable ETLx This bit enables/disables the falling edge event as edge event as set condition for the status flag FL or as possible trigger pulse for TRxy. 0 _B A falling edge is not considered as edge event 1 _B A falling edge is considered as edge event |
| OCS | [6:4] | rw | Output Channel Select for ETLx Output Trigger Pulse This bit field defines which Output Channel OGUy is targeted by an enabled trigger pulse TRxy. 000 _B Trigger pulses are sent to OGU0 001 _B Trigger pulses are sent to OGU1 010 _B Trigger pulses are sent to OGU2 011 _B Trigger pulses are sent to OGU3 Others: Reserved, do not use this combination |
| FL | 7 | rwh | Status Flag for ETLx This bit represents the status flag that becomes set or cleared by the edge detection. 0 _B The enabled edge event has not been detected 1 _B The enabled edge event has been detected |
| SS | [9:8] | rw | Input Source Select for ERSx This bit field defines which logical combination is taken into account as ERSxO. 00 _B Input A without additional combination 01 _B Input B without additional combination 10 _B Input A OR input B 11 _B Input A AND input B |
| NA | 10 | rw | Input A Negation Select for ERSx This bit selects the polarity for the input A. 0 _B Input A is used directly 1 _B Input A is inverted |
| NB | 11 | rw | Input B Negation Select for ERSx This bit selects the polarity for the input B. 0 _B Input B is used directly 1 _B Input B is inverted |
| 0 | [31:12] | r | Reserved Read as 0; should be written with 0. |

Event Request Unit (ERU)

ERU0_EXOCONx (x=0-3)

Event Output Trigger Control x

($20_H + 4 \cdot x$)

Reset Value: 0000 0008_H

| Field | Bits | Type | Description |
|-------------|-------|------|--|
| ISS | [1:0] | rw | Internal Trigger Source Selection This bit field defines which input is selected as peripheral trigger input for OGUy. 00 _B The peripheral trigger function is disabled 01 _B Input ERU_OGUy1 is selected 10 _B Input ERU_OGUy2 is selected 11 _B Input ERU_OGUy3 is selected |
| GEEN | 2 | rw | Gating Event Enable Bit GEEN enables the generation of a trigger event when the result of the pattern detection changes from match to miss or vice-versa. 0 _B The event detection is disabled 1 _B The event detection is enabled |
| PDR | 3 | rh | Pattern Detection Result Flag This bit represents the pattern detection result. 0 _B A pattern miss is detected 1 _B A pattern match is detected |

Event Request Unit (ERU)

| Field | Bits | Type | Description |
|----------------------------|---------------------|------|---|
| GP | [5:4] | rw | Gating Selection for Pattern Detection Result This bit field defines the gating scheme for the service request generation (relation between the OGU output ERU_PDOUTy and ERU_GOUTy). 00 _B ERU_GOUTy is always disabled and ERU_IOUTy can not be activated 01 _B ERU_GOUTy is always enabled and ERU_IOUTy becomes activated with each activation of ERU_TOUTy 10 _B ERU_GOUTy is equal to ERU_PDOUTy and ERU_IOUTy becomes activated with an activation of ERU_TOUTy while the desired pattern is detected (pattern match PDR = 1) 11 _B ERU_GOUTy is inverted to ERU_PDOUTy and ERU_IOUTy becomes activated with an activation of ERU_TOUTy while the desired pattern is not detected (pattern miss PDR = 0) |
| IPENx (x = 0-3) | 12+x | rw | Pattern Detection Enable for ETLx Bit IPENx defines whether the trigger event status flag EXICONx.FL of ETLx takes part in the pattern detection of OGUy. 0 _B Flag EXICONx.FL is excluded from the pattern detection 1 _B Flag EXICONx.FL is included in the pattern detection |
| 0 | [31:16] , [11:6] | r | Reserved Read as 0; should be written with 0. |

6.10 Interconnects

This section describes how the ERU0 module is connected within the XMC1100 system.

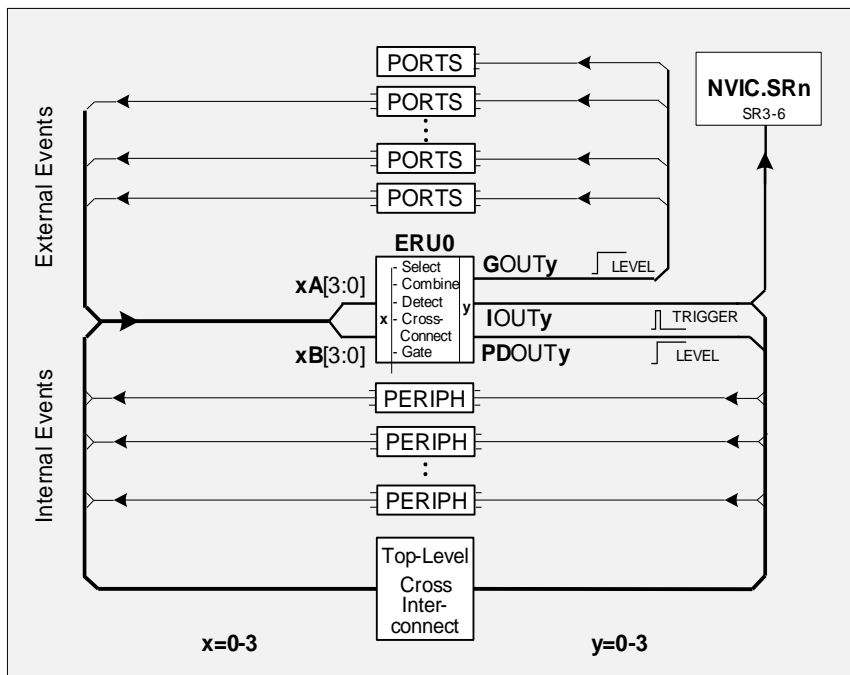

Figure 6-6 ERU Interconnects Overview

6.10.1 ERU0 Connections

The following table shows the ERU0 connections.

On-Chip Memories

7 Memory Organization

This chapter provides description of the system memory organization, memory accesses and memory protection strategy.

References

[5] Cortex®-M0 User Guide, ARM DUI 0497A (ID112109)

7.1 Overview

The Memory Map in XMC1100 is based on standard ARM Cortex-M0 system memory map.

7.1.1 Features

The Memory Map implements the following features:

- Compatibility with standard ARM Cortex-M0 CPU [\[5\]](#)
- Full compatibility across entire XMC1000 Family

7.1.2 Cortex-M0 Address Space

The system memory map defines several regions. Address boundaries of each of the regions are determined by the Cortex-M0 core architecture.

Memory Organization

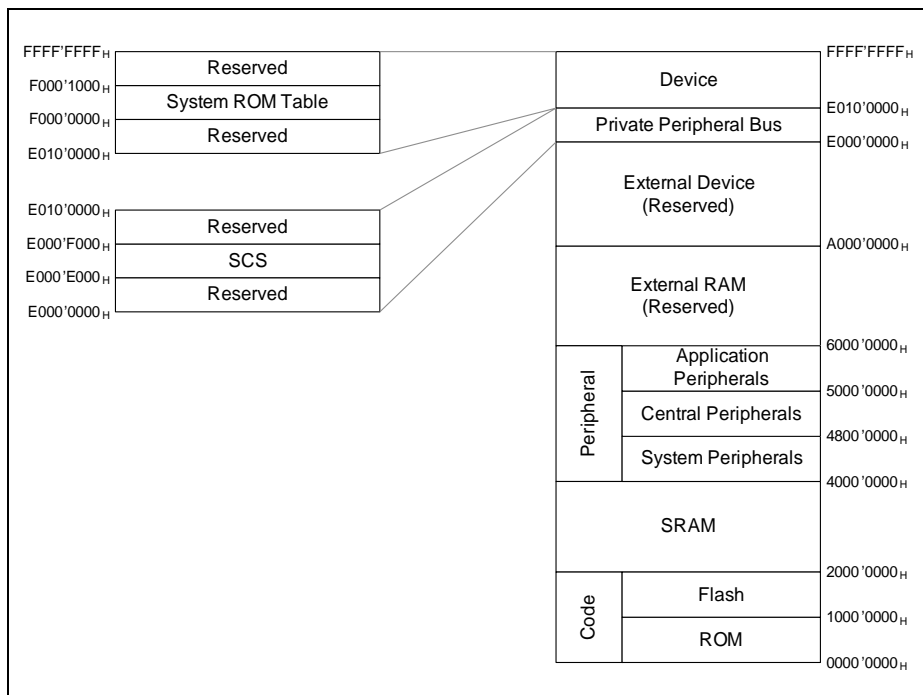

Figure 7-1 XMC1100 Address Space

7.2 Memory Regions

The XMC1100 device-specific address map contains on-chip memories and peripherals. The memory regions for XMC1100 are described in [Table 7-1](#).

Table 7-1 Memory Regions

| Start (hex) | End (hex) | Size (hex) | Space name | Usage |
|-------------|-----------|------------|------------|--------------------------|
| 00000000 | 1FFFFFFF | 20000000 | Code | ROM Firmware, Flash |
| 20000000 | 3FFFFFFF | 20000000 | SRAM | Fast internal SRAM |
| 40000000 | 47FFFFFF | 08000000 | Peripheral | System Peripherals group |

Memory Organization

Table 7-1 Memory Regions (cont'd)

| Start (hex) | End (hex) | Size (hex) | Space name | Usage |
|-------------|-----------|------------|------------------------|-------------------------------|
| 48000000 | 4FFFFFFF | 08000000 | Peripheral | Central Peripherals group |
| 50000000 | 57FFFFFFF | 08000000 | Peripheral | Application Peripherals group |
| 58000000 | 5FFFFFFF | 08000000 | Peripheral | reserved |
| 60000000 | 9FFFFFFF | 40000000 | External SRAM | reserved |

7.3 Memory Map

Table 7-2 defines detailed system memory map of XMC1100 where each individual peripheral or memory instance implement its own address spaces. For detailed register description of the system components and peripherals, please refer to respective chapters of this document.

Note: Depending on the device variant, not all peripherals and memory address ranges may be available.

Memory Organization
Table 7-2 XMC1100 Memory Map

| Address space | Address Range | Description | Access Type ¹⁾ | |
|--------------------|---|------------------------------------|---------------------------|-------|
| | | | Read | Write |
| Code | 00000000 _H - 00000BFF _H | ROM (user-readable) | U, PV | nBE |
| | 00000C00 _H - 00001FFF _H | ROM (non-user-readable) | BE | BE |

Memory Organization

- 1) For address ranges taken up by peripherals, the access type for each address in the range may differ from that shown in the table. Refer to respective chapters for details.
- 2) The address range 2000'0000_H to 2000'01FF_H will be overwritten by start-up software during device start-up.

7.4 Memory Access

This section describes the memory accesses to the different type of memories in XMC1100.

7.4.1 Flash Memory Access

The XMC1100 provides up to 64 Kbytes of Flash memory for instruction code or constant data, starting at address 1000'1000_H. This excludes Flash sector 0, which is used to store system information and is always read only.

The Flash memory will insert waitstates during memory read automatically if needed.

For details of Flash memory access, refer to the Flash Architecture chapter.

7.4.2 SRAM Access

The XMC1100 provides 16 Kbytes of SRAM for instruction code or constant data, as well as system variables such as the system stack, starting at address 2000'0000_H.

The SRAM supports 8-bit, 16-bit and 32-bit writes, and generates one parity bit for each 8 bits of written data. A read operation will check for parity errors on the 32-bit read data. Accesses to the SRAM require no wait states.

The 16 Kbytes of SRAM is logically divided into four blocks of 4 Kbytes each. Accesses to blocks 1, 2 and 3 can be disabled and enabled again during run-time with the peripheral privilege access scheme. See PAU chapter for details.

Note: The address range 2000'0000_H to 2000'01FF_H will be overwritten by the start-up software during device start-up. Therefore, these addresses should not be targeted during the download of code/data by the bootstrap loader into the SRAM nor should they store critical data that are still needed by the application after a system reset or SW master reset.

7.4.3 ROM Access

The XMC1100 provides 8 Kbytes of ROM, which contains the startup software, vector table and user routines.

Read accesses to the ROM require no wait states.

7.5 Memory Protection Strategy

Two aspects of memory protection are considered:

1. Intellectual Property (IP) Protection
2. Memory Access Protection during Run-time

The memory protection measures available in XMC1100 are listed in [Table 7-3](#).

Table 7-3 Memory Protection Measures

| Protection Aspects | Protection Measures | Protection Target |
|--------------------------|--|---|
| IP protection | Blocking of unauthorized external access | Flash memory contents |
| Memory access protection | Bit protection scheme | Specific system-critical registers/bit fields |
| | Peripheral privilege access control | Specific address ranges; each range can be controlled independently |

7.5.1 Intellectual Property (IP) Protection

IP protection refers to the prevention against unauthorized read out of critical data and user IP from Flash memory.

7.5.1.1 Blocking of Unauthorized External Access

In XMC1100, the Boot Mode Index (BMI) is used to control the boot options such that once the BMI is programmed to enter user mode (productive), it is not allowed to enter the other boot modes without an erase of the complete user Flash (including sector 0).

Therefore, boot options that load and execute external code, including unauthorized code that might read out the Flash memory contents, will be blocked and only user code originating from the Flash memory can be executed.

7.5.2 Memory Access Protection during Run-time

Memory access protection refers to the prevention against unintended write access on a memory address space during run-time.

7.5.2.1 Bit Protection Scheme

The bit protection scheme prevents direct software writing of selected register bits (i.e., protected bits) using the PASSWD register in the SCU module. When the bit field MODE is 11_B, writing 10011_B to the bit field PASS opens access to writing of all protected bits, and writing 10101_B to the bit field PASS closes access to writing of all protected bits. In both cases, the value of the bit field MODE is not changed even if PASSWD register is written with 98_H or A8_H. It can only be changed when bit field PASS is written with 11000_B, for example, writing 0000'00C0_H to PASSWD register disables the bit protection scheme.

Access is opened for maximum 32 MCLKs if the “close access” password is not written. If “open access” password is written again before the end of 32 MCLK cycles, there will be a recount of 32 MCLK cycles.

Table 7-4 shows the list of protected bit in XMC1100.

Table 7-4 List of Protected Register Bit Fields

| Register | Bit Field |
|-----------------------|--|
| SCU_CLKCR, SCU_CLKCR1 | FDIV, IDIV, PCLKSEL, RTCLKSEL, ADCCLKSEL |
| SCU_ANAOSCHPCTRL | MODE, SHBY |
| SCU_CGATSET0 | All bits |
| SCU_CGATCLR0 | All bits |
| VADC0_ACCPROT0 | All bits |
| VADC0_ACCPROT1 | All bits |

Write to all protected registers except VADC0_ACCPROT[1:0], without opening access through bit field PASS, will be ignored. No bus error will be generated. User should read back the register value to ensure the write has taken place.

Write to VADC0_ACCPROT[1:0], without opening access through bit field PASS, will trigger a hard fault. If an interrupt occurs immediately after the access is opened and the interrupt service routine requires more than 32 MCLK cycles, the write to the register will happen after the access is closed and thereby, triggering a hard fault. To avoid this, interrupts should be disabled before writing to these two registers.

The PASSWD register is also described in the SCU chapter.

SCU_PASSWD

Password Register

(4001 0024_H)

Reset Value: 0000 0007_H

| Field | Bits | Type | Description |
|--------------|--------|------|---|
| MODE | [1:0] | rw | Bit Protection Scheme Control Bits 00 _B Scheme disabled - direct access to the protected bits is allowed. 11 _B Scheme enabled - the bit field PASS has to be written with the passwords to open and close the access to the protected bits. (Default) Others: Scheme enabled, similar to the setting for MODE = 11 _B . These two bits cannot be written directly. To change the value between 11 _B and 00 _B , the bit field PASS must be written with 11000 _B . Only then will the MODE bit field be registered. |
| PROTS | 2 | rh | Bit Protection Signal Status Bit This bit shows the status of the protection. 0 _B Software is able to write to all protected bits. 1 _B Software is unable to write to any of the protected bits. |
| PASS | [7:3] | w | Password Bits This bit protection scheme only recognizes the following three passwords: 11000 _B Enables writing of the bit field MODE. 10011 _B Opens access to writing of all protected bits. 10101 _B Closes access to writing of all protected bits. |
| 0 | [31:8] | r | Reserved |

7.5.2.2 Peripheral Privilege Access Control

All CPU accesses are privileged accesses. In XMC1100, a separate scheme called Peripheral Privilege Access Control, which allows a peripheral's memory address space to be disabled to block any unintended write or read access, is provided. The address space can be re-enabled when necessary.

Refer to the PAU chapter for details.

7.6 Service Request Generation

Memory modules and other system components are capable of generating error responses indicated to the CPU as bus error exceptions or interrupts.

Types of Error Causes

- Unsupported Access Mode
- Access to Invalid Address
- Data integrity Error (memories only)

Errors that cannot be indicated with bus errors get indicated with service requests that get propagated to the CPU as interrupts.

Unsupported Access Modes

Unsupported access modes can be classified in various ways and are usually specific to the module that access is performed to. Typical examples of unsupported access modes are write access to read-only type of address mapped resources, protected memory regions. For module specific limitations please refer to individual module chapters.

Invalid Address

Accesses to invalid addresses result in error responses. Invalid addresses are defined as those that do not mapped to any valid resources. This applies to single addresses and to wider address ranges. Some invalid addresses within valid module address ranges may not produce error responses and this is specific to individual modules.

Data Integrity Error

Accesses to corrupted data in the memories result in either ECC (Error Correction Code) (ECC) or parity errors. The occurrence of such errors get signaled to the system through an SCU interrupt.

7.7 Debug Behaviour

The bus system in debug mode allows debug probe access to all system resources. No special handling of HALT mode is implemented and all interfaces respond with a valid bus response upon accesses.

7.8 Power, Reset and Clock

The bus system clocking scheme enables stable system operation and accesses to system resources for all valid system clock rates.

7.9 Initialization and System Dependencies

No initialization is required for the memory system from user point of view. All valid memories are available after reset. Some peripherals may need to be initialized (e.g. disable clock gating) before they can be accessed. For details please refer to individual peripheral chapters.

8 Flash Architecture

This chapter describes the non volatile memory (NVM) module.

8.1 Overview

The XMC1100 has an embedded user-programmable NVM for storage of user code and data.

8.1.1 Features

The NVM has the following features:

- Reading by word, writing by block and erasing by page (256 bytes) or sector (4 Kbytes).
- Fast personalization support.
- Automatic verify support.
- Up to 50,000 erase cycles per page.
- Minimum data retention of 10 years in cells that were never previously programmed.
- Flash programming voltage generated on-chip.
- Configurable erase and write protection.
- Power saving sleep mode.
- Incremental write without erase for semaphores.

8.2 Definitions

Throughout the document the terms NVM (Non Volatile Memory) and Flash are used as synonyms, disregarding the fact that NVM describes a broader class of memories, where the described Flash is only a special case.

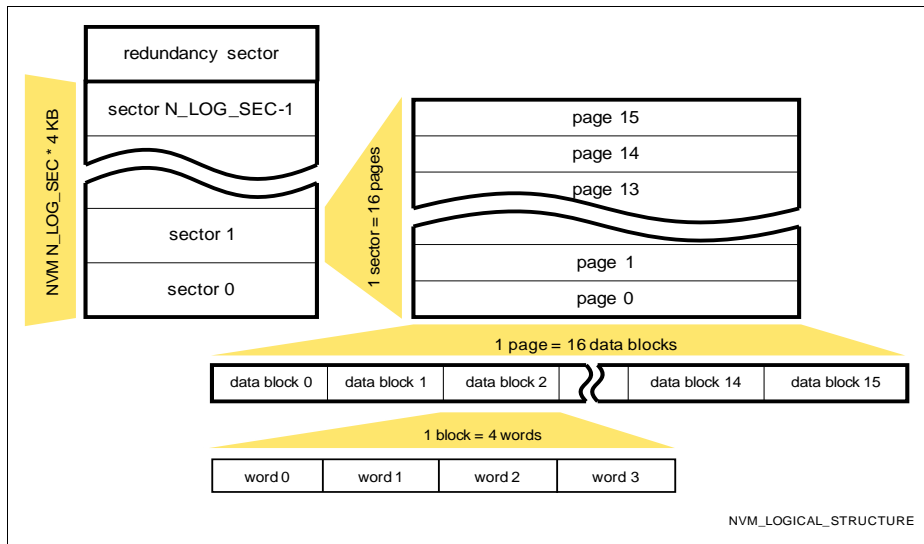

Figure 8-1 Logical structure of the NVM module

8.2.1 Logical and Physical States

Erasing

The erased state of a cell is '1'. Forcing an NVM cell to this state is called erasing. Erasing is possible with a granularity of a page (see below).

Writing

The written state of a cell is '0'. Changing an erased cell to this state is called writing. Writing is possible with a granularity of a block (see below).

Programming

The combination of erasing and writing is called programming. Programming often means also writing a previously erased page.

*Note: The termini **write** and **writing** are also used for accessing special function registers. The meaning depends therefore on the context.*

8.2.2 Data Portions

Word

A word consists of 32 bits. A word represents the data size which is read from or written to the NVM module within one access cycle.

Block

A block consists of 4 words (128 bit data, extended by 4 bit parity, and 6 bit ECC). A block represents the smallest data portion that can be written.

Page

A page consists of 16 blocks.

Sector

A sector consists of 16 pages.

8.2.3 Address Types

Physical Address

Address of the CPU system.

Base Address or Memory Base Address

Physical address of the lower boundary for memory accesses of an NVM module.

Logical Address

Memory address offset inside the NVM module: If the memory is addressed, the logical address is the physical address subtracted by the base address of the module.

Sector Address

Module specific part of the logical address specifying the sector, for calculation see [Section 8.3.1](#).

Page Address

Module specific part of the logical address, for calculation see [Section 8.3.1](#).

8.2.4 Module Specific Definitions

The following table defines NVM specific constants used throughout this chapter.

Table 8-1 Module Specific Definitions

| | | |
|-------------------------|--------------|--|
| Module size [KB] | 204 | |
| Constant name | Value | Comment |
| N_BLOCKS | 16 | Number of blocks per page |
| N_PAGES | 16 | Number of pages per sector |
| N_SECTORS | 52 | Number of sectors including redundancy |
| N_LOG_SEC | 51 | Number of sectors excluding redundancy |

8.3 Module Components

8.3.1 Memory Cell Array

The non-volatile memory cells are organized in sectors, which consist of pages, which on their part are structured in blocks.

A logical memory address *addr* has the following structure:

Figure 8-2 Decomposition of Logical Address

- *addr*[1:0] = word offset, for a memory address undefined and ignored
- *addr*[3:2] = word address
- *addr*[7:4] = block address
- *addr*[11:8] = page address
- *addr*[17:12] = sector address.

The memory subsystem always accesses whole words, therefore the word offset is ignored by the NVM module.

8.3.1.1 Page

Each page consists of 16 data blocks of 138 bits each (including parity bits and ECC bits).

A page is the granularity of data that can be erased in the cell array.

Figure 8-3 Structure of a Page

8.3.1.2 Sector

16 pages form a sector.

The whole cell array is build of 52 sectors.

8.4 Functional Description

The NVM module supports read and write accesses to the memory and to the special function registers (SFRs). No read-modify-write mechanism is supported for SFRs.

The main tasks of the NVM module are reading and writing from/to the memory array.

8.4.1 SFR Accesses

Reading the special function registers is possible in every mode of the NVM module.

Register write is not possible while the state machine is busy. The write is stalled in this case. For other exceptions see [Section 8.8.2.2](#).

8.4.2 Memory Read

The NVM memory can be read with a minimum granularity of a word provided that the word is in the memory address range of the module.

If the word is not within the memory address range of the NVM module, the module does not react at all and a different memory module may handle the access.

Memory read accesses are only possible while no FSM procedure (erase, write, verify, sleep or wake-up) is in progress. A memory read access while the FSM is busy is stalled until the FSM is idle again. Then the access is carried out. Such a stall will also stop the CPU from executing code.

Per default the XMC1100 devices use a configuration with adaptive wait states for read accesses to the flash memory, dynamically adapting to the system frequency and flash access timing without user software interaction.

8.4.2.1 Flash read access with fixed wait states

It is possible to configure the XMC1100 devices to apply fixed wait states to each flash read access, improving determinism of program execution from flash. The required number of wait states depends on the system frequency f_{MCLK} , as defined in the parameter $N_{FWSFLASH}$. The number of wait states can be configured with the bit [NVMCONF.WS](#). The selection of adaptive or fixed wait states is done with the bit [CONFIG1.WS](#).

Attention: Any write operation to the register [CONFIG1](#) to switch between adaptive and fixed wait states configuration must only modify the bit [CONFIG1.FIXWS](#). Changing other bits in [CONFIG1](#) can lead to unpredictable results.

Attention: Before and after the fixed wait states configuration or the system frequency f_{MCLK} is changed, the number of selected wait states must always comply to the parameter $N_{FWSFLASH}$.

Below is a code snippet defining the register addresses, configuring one wait state and then switching to operation with one fixed wait state.

Example

```
// Headers and variables to fix number of wait states to "1"
#define ADDR1 0x40050008 //Address of NVM_NVMCONF
uint32_t * NVM_NVMCONF = (uint32_t *) ADDR1;
#define ADDR2 0x40050048 //Address of NVM_CONFIG1
uint32_t * NVM_CONFIG1 = (uint32_t *) ADDR2;

// init sequence to fix number of wait states to "1"
*NVM_NVMCONF = *NVM_NVMCONF | 0x1000; //Set .WS bit => 1WS
*NVM_CONFIG1 = *NVM_CONFIG1 | 0x0800; //Set .FIXWS bit => fixed
WS scheme
```

8.4.3 Memory Write

From the user's viewpoint data is written directly to the memory array. Module internally one block is buffered and the ECC bits are calculated. Then a finite state machine is started that writes the ECC and data bits to the memory field.

Writing does not support wrap-around, i.e. writing of a block has always to start with word 0 of the selected block and then automatically continues in ascending order up to word 3.

Since a block has to be written in four word writing steps, a special procedure has to be followed to transfer complete block data to the NVM: Writing of a block has always to start with word 0 of the addressed block. The following three writes need to address the other three words of the same block in ascending order. If this rule is not observed, the already provided words are discarded. If in this case the last provided word is addressing a word 0, this word is already accepted as the first word of a new block write procedure. Intermediate read operations do not influence the write data transfer. Intermediate read operations targeting the same address as the interrupted write operation are served from the memory array, i.e. do not read back the already transferred write data.

To write to the memory array, the NVM module has to be set to one-shot or continuous write mode by setting the SFR **NVMPROG** to the corresponding value. Data to be written can now be written to the desired address. It is not checked, if the addressed block was erased before. Writing to a non erased block leads to corrupted data since writing can only clear bits but not set any bits. Reading such a block will lead most probably to an ECC fault.

A write access to the NVM when not in write mode does not trigger an exception or interrupt. The data is lost. Writes to the NVM are also used to trigger other operations which are described in the following subsections. Similarly, a write access to the NVM module has no effect and the data is lost when a protected sector is addressed (see [Section 8.4.7](#)).

Depending on the settings of **NVMPROG**, an automatic verify is performed (see [Section 8.4.6](#)).

In case of a one-shot write, write mode is automatically left. In case of continuous write mode, further write operations to new addresses can follow, until the write mode is explicitly left. Continuous write operations can target blocks within the complete memory without any restriction regarding sector or page borders.

8.4.4 Memory Erase

Only whole pages can be physically erased, i.e. all bits of the addressed page are physically set to '1'.

To erase a page in the memory field, the NVM module has to be set to one-shot or continuous page erase mode by setting the SFR **NVMPROG** to the corresponding value. A write access to a memory location specifies the address of the page to be erased and triggers the erase.

A write access to the NVM when not in page erase mode does not trigger an exception or interrupt because they are also used to trigger other operations; as described in this section. Similarly, no erase is triggered when a protected sector is addressed (see [Section 8.4.7](#)).

In case of a one-shot page erase, page erase mode is automatically left. In case of continuous page erase mode, further page erase operations can follow, until the page erase mode is explicitly left.

8.4.5 Sector Erase

Additionally, whole sectors consisting of 16 pages can be physically erased in parallel, i.e. all bits of the addressed sector are physically set to '1'.

To erase a sector in the memory array, the NVM module has to be set to one-shot or continuous sector erase mode by setting the SFR **NVMPROG** to the corresponding value. Writing arbitrary data to a memory location specifies the address of the sector to be erased.

A write access to the NVM when not in sector erase mode does not trigger an exception or interrupt because it is also used to trigger other operations; as described in this section. Similarly, no erase is triggered when a protected sector is addressed (see [Chapter 8.4.7](#)).

In case of a one-shot sector erase, sector erase mode is automatically left. In case of continuous sector erase mode, further sector erase operations can follow, until the sector erase mode is explicitly left.

8.4.6 Verify

The data written as described in [Section 8.4.3](#) can be verified automatically. The written data in the cell array can be automatically compared to the data still available in the module internal buffer. This is automatically performed two times with hardread written and hardread erased. These hardread levels provide some margin compared to the normal read level to ensure that the data is really programmed with suitably distinct levels for written and erased bits. The verification result can be read at SFR **NVMSTATUS**.

Stand-alone verify operations can also be started by setting the SFR **NVMPROG** to the corresponding value. In this case, data written to a memory location is compared with the content of the memory field at the specified address. The comparison here is performed just once with a read level chosen before from normal read, hardread written and hardread erased.

A write access to the NVM when not in verification mode does not trigger an exception or interrupt because it is also used to trigger other operations; as described in this section. Similarly, a write access to the NVM module has no effect, when a protected sector is addressed (see [Section 8.4.7](#)).

In case of a one-shot verify, verify mode is automatically left. In case of continuous verify mode, further verify operations can follow, until the verify mode is explicitly left.

Note: A continuous write operation without automatic verification, followed by two stand-alone verifications with 'hardread written' and 'hardread erased', is faster than a write operation with continuous automatic verification, since in the second case for every block write the hardread level has to be changed twice, whereas in the first case this change is performed only two times for the complete write data.

On the other hand, for the continuous automatic verification the reference data for the verification is directly available within the NVM module, whereas for the stand-alone verification the reference data needs to be provided again by the CPU.

8.4.7 Erase-Protection and Write-Protection

By setting **NVMCONF.SECPROT**, a configurable number of sectors can be selected to be protected from any modification, i.e. a range of sectors starting with sector 0 can be defined to be erase-protected and write-protected.

8.5 Redundancy

To increase the production yield, the NVM module contains redundancy. Redundancy is transparent to the user.

8.6 Properties and Implementation of Error Correcting Code (ECC)

The error correcting code (ECC) for the data blocks is a one-bit error correction and a (partial) double-bit error detection for every data block of 128 bit, which uses 4 parity bits and 6 ECC bits in addition to the protected 128 data bits. The correct ECC bits for every block are generated automatically when the data is written.

8.7 Service Request Generation

The NVM module supports immediate error and status information to the user by interrupt generation.

A NVM interrupt can be issued because of the following events:

- Completion of:
 - NVM operations started through NVMPROG.ACTION (except for verify-only sequence)
 - NVM wake-up sequence
- NVM ECC double-bit error

The NVM interrupt request is generated to the CPU through the SCU. Therefore, related interrupt control bits are located in the SCU but with the following exceptions:

- There are two sets of NVM ECC double-bit error status flag and clear status bit:
 - NVMSTATUS.ECC2READ and NVMPROG.RSTECC in NVM module
 - SCU_RAWSR.FLECC2I and SCU_SRCLR.FLECC2I in SCU module
- It is sufficient to use just one of the two sets and ignore the other.
- The interrupt enable bit for the NVM operation complete interrupt is located only in the NVMCONF register.

8.8 Power, Reset and Clock

The following sections describe the power, reset and clock sources of the NVM module.

8.8.1 Power Supply

The NVM module sources all voltages required for read, program and erase operations from the on-chip Embedded Voltage Regulator (EVR).

The standard V_{DDC} is used for all digital control functions.

8.8.2 Power Saving Modes

The NVM module supports the following power saving modes. The modes differ in power consumption and in the time to restart the memory.

8.8.2.1 NVM Idle Mode

Idle mode is entered after reset after charging the pumps. In idle mode the power consumption is less than during a memory read access or write access.

Any operation of the NVM module (SFR access or memory access) can be started from idle mode without time delay.

8.8.2.2 NVM Sleep Mode

Entering and leaving NVM sleep mode requires special state machine sequences, which need some time. Therefore, besides SFR accesses, the NVM module cannot be used immediately after wake-up from sleep mode, as indicated by **NVMSTATUS.BUSY**.

NVM sleep mode is entered via WFE/WFI when Flash Power down is activated, see SCU chapter. Alternatively, sleep mode for the NVM module can be triggered by writing the respective bit in SFR **NVMCONF**.

In NVM sleep mode only the SFR **NVMCONF** can be read and written, all other SFRs can only be read. No memory access is possible in sleep mode.

8.8.3 Reset

The NVM module is reset with the system reset.

8.8.4 Clock

The NVM module is operating at the same clock speed as main clock, MCLK.

8.9 Registers

Table 8-3 shows a complete list of the NVM special function registers.

Table 8-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| NVM | 4005 0000 _H | 4005 00FF _H | |

Table 8-3 Registers Overview

| Register Short Name | Register Long Name | Offset Address | Page Number |
|---------------------|----------------------------------|-------------------|---------------------------|
| NVMSTATUS | NVM Status Register | 0000 _H | Page 8-12 |
| NVMPROG | NVM Programming Control Register | 0004 _H | Page 8-14 |
| NVMCONF | NVM Configuration Register | 0008 _H | Page 8-16 |

The register is addressed wordwise.

Reading an SFR is not blocked, while the NVM module is busy. If the SFR value depends on the completion of an NVM sequence, **NVMSTATUS.BUSY** must be polled for 0_B, before the SFR is read. Otherwise, reading the SFR might yield a value that is not updated yet.

8.9.1 NVM Registers

NVM Status Register

NVMSTATUS

NVM Status Register

(0000_H)

Reset Value: 0002_H

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|---|---|------------|------------------|------------------|------|---|-----------|----------|
| 0 | | | | | | | | | WRP ERR | ECC 2RE AD | ECC 1RE AD | VERR | | SLE EP | BUS Y |
| r | | | | | | | | | r | r | r | r | | r | r |

| Field | Bits | Type | Description |
|----------|------|------|--|
| 0 | 15:7 | r | Reserved Read as 0. |
| WRPERR | 6 | r | Write Protocol Error The flag accumulates write protocol violations during the last 4-word write operations (for write or verify). It is also set when a triggered operation was ignored because of write protection. The correct protocol is defined in Section 8.4.3 . It is reset by hardware when NVMPROG.RSTECC is written. 0 _B WRPROTOK , No write protocol failure occurred. 1 _B WRPROTFAIL , At least one write protocol failure was detected. |
| ECC2READ | 5 | r | ECC2 Read¹⁾ The flag accumulates ECC two bit failure during memory read operations. It is reset by hardware when NVMPROG.RSTECC is written. 0 _B ECC2RDOK , No ECC two bit failure during memory read operations. 1 _B ECC2RDFAIL , At least one ECC two bit failure was detected. |

| Field | Bits | Type | Description |
|-----------------|------|------|---|
| ECC1READ | 4 | r | ECC1 Read¹⁾ The flag accumulates ECC single bit failure during the last memory read operations. It is reset by hardware when NVMPROG.RSTECC is written. 0 _B ECC1RDOK , No ECC single bit failure occurred. 1 _B ECC1RDFAIL , At least one ECC single bit failure was detected and corrected. |
| VERR | 3:2 | r | Verify Error The flag is reset by hardware, when NVMPROG.RSTVERR is written. The flag is also reset, when write mode or verify-only mode are entered, i.e. NVMPROG.ACTION.OPTYPE = 0001 _B or NVMPROG.ACTION.VERIFY = 11 _B . The flag accumulates, i.e. VERR is updated every time a value higher than the current value is required, until write mode or verify-only mode are left (automatically in case of a one-shot write operation). Information on number of fail bits during verify procedure(s): 00 _B NOFAIL , No fail bit. 01 _B ONEFAIL , One fail bit in one data block. 10 _B TWOFAIL , Two fail bits in two different data blocks. 11 _B MOREFAIL , Two or more fail bits in one data block, or three or more fail bits overall. |
| SLEEP | 1 | r | Sleep Mode 0 _B READY , NVM not in sleep mode, and no sleep or wake up procedure in progress. 1 _B SLEEP , NVM in sleep mode, or busy due to a sleep or wake up procedure. |
| BUSY | 0 | r | Busy 0 _B READY , The NVM is not busy. Memory reads from the cell array and register write accesses are possible. 1 _B BUSY , The NVM is busy. Memory reads and register write accesses are not possible. |

1) If a block is read from the field that contains two or more parity errors ECC1 and ECC2 errors may be flagged simultaneously.

NVM Programming Control Register

NVMPROG

NVM Programming Control Register (0004_H)

Reset Value: 0000_H

| ACTION | 7:0 | rw | <p>ACTION: [VERIFY, ONE_SHOT, OPTYPE]</p> <p>This field selects an erase, write, or verify operation. See also More details on ACTION. ACTION is a concatenation of three bit fields: ACTION[7:6] = VERIFY, ACTION[5:4] = ONE_SHOT and ACTION[3:0] = OPTYPE. OPTYPE defines the following operations:</p> <p>0000_B: idle or verify-only, that depends on the setting of VERIFY;</p> <p>0001_B: write;</p> <p>0010_B: page erase.</p> <p>0100_B: sector erase.</p> <p>ONE_SHOT is a parameter of OPTYPE with the following values:</p> <p>01_B: once or</p> <p>10_B: continuously.</p> <p>In case of 01_B, ACTION is automatically reset to idle mode after operation has been performed.</p> <p>VERIFY defines a second parameter of OPTYPE:</p> <p>01_B: verification of written data with hardread levels after every write operation,</p> <p>10_B: no verification, 11_B: verification of array content.</p> <p>The following operations are defined, other values are interpreted as 00_H</p> <p>00_H , Idle state, no action triggered. Writing 00_H exits current mode.</p> <p>51_H , Start one-shot write operation with automatic verify.</p> <p>91_H , Start one-shot write operation without verify.</p> <p>61_H , Start continuous write operation with automatic verify of every write.</p> <p>A1_H , Start continuous write operation without verify.</p> <p>92_H , Start one-shot page erase operation.</p> <p>94_H , Start one-shot sector erase operation.</p> <p>A4_H , Start continuous sector erase operation.</p> <p>A2_H , Start continuous page erase operation.</p> <p>D0_H , Start one-shot verify-only: Written data is compared to array content.</p> <p>E0_H , Start continuous verify-only: Written data is compared to array content.</p> |

More details on ACTION

The operation selected by ACTION is performed, when a write to the NVM address range is performed, which defines the address (and block data) for the operation. Afterwards, in case of a one-shot operation, ACTION is automatically reset.

Verification results can be read at **NVMSTATUS.VERR**.

ACTION can only be changed when the current value of ACTION is 00_H, otherwise ACTION is set to 00_H. Once ACTION is not idle, ACTION can only be written again with its current value; any other value leads to a reset of ACTION.

Only write operations can be automatically verified. Page erase operations cannot use automatic verify, they must be started with ACTION.VERIFY = 10_B.

If the correct erasing of a page or sector is to be verified, a separate sequence using ACTION.VERIFY = 11_B has to be started.

A verify operation requires the provision of the data for a complete block and always includes the ECC bits. The ECC bits for every block are generated automatically when the data is written.

A verify operation started with ACTION.VERIFY = 01_B is automatically performed with both hardread written and hardread erased levels.

A verify operation started with ACTION.VERIFY = 11_B is performed with the single hardread level defined by **NVMCONF.HRLEV** at this starting time.

A sequence started by setting ACTION will set **NVMSTATUS.BUSY** only after the transfer of the address (and block data) is performed. The end of the sequence can be detected either by polling NVMSTATUS.BUSY or by waiting for an NVM interrupt (not for verify-only sequence).

Entering sleep mode resets ACTION.

NVM Configuration Register

NVMCONF is the only SFR that can be written while the module is in sleep mode. This is necessary to enable the use of NVM_ON = 0_B to go to sleep mode and of NVM_ON = 1_B to wake-up again.

NVMCONF

NVM Configuration Register (0008_H) **Reset Value: 9000_H**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---------------|---------------|----------|-----------|----------------|----|---|---|---|---|---|---|----------|--------------|----------|---|
| NVM_ON | INT_ON | 0 | WS | SECPROT | | | | | | | | 0 | HRLEV | 0 | |
| rw | rw | rw | rw | rw | | | | | | | | r | rw | rw | |

| Field | Bits | Type | Description |
|----------------|------|------|---|
| NVM_ON | 15 | rw | NVM On When cleared, no software code can be executed anymore from the NVM, until it is set again. I.e., already the software code that initiates the change in NVM_ON itself may not reside in the NVM, otherwise the software is stalled forever. 0 _B SLEEP , NVM is switched to or stays in sleep mode. 1 _B NORM , NVM is switched to or stays in normal mode. |
| INT_ON | 14 | rw | Interrupt On When enabled the completion of a sequence started by setting NVMPROG.ACTION (write or erase sequence) will be indicated by NVM interrupt. The same is true for the wake-up sequence. 0 _B INTOFF , No NVM ready interrupts are generated. 1 _B INTON , NVM ready interrupts are generated. |
| 0 | 13 | rw | Reserved for Future Use Must be written with 0 to allow correct operation. |
| WS | 12 | rw | Number of fixed Wait States Defines the number of fixed wait states when NVM_CONFIG1.FIXWS = 1 _B . 0 _B 0 fixed wait states. 1 _B 1 fixed wait state. |
| SECPROT | 11:4 | rw | Sector Protection¹⁾ This field defines the number of write, erase, verify protected sectors, starting with physical sector 0. |
| 0 | 3 | r | Reserved Read as 0; should be written with 0. |
| HRLEV | 2:1 | rw | Hardread Level²⁾ Defines single hardread level for verification with NVMPROG.ACTION.VERIFY = 11 _B : 00 _B NR , Normal read 01 _B HRW , Hardread written 10 _B HRE , Hardread erased 11 _B RFU , Reserved for Future Use |
| 0 | 0 | rw | Reserved for Future Use Must be written with 0 to allow correct operation. |

- 1) For SECPROT > 0, SECPROT defines the number of protected sectors. The sectors 0 to SECPROT-1 cannot be written, erased, or verified. All writes that target the protected sectors are accepted, but are internally ignored.
- 2) HRLEV defines the hardread level for a stand-alone verification sequence started with NVMPROG.ACTION.VERIFY = 11_B. This hardread level is used until the end of the verification sequence. HRLEV may not be changed in between.

Configuration 1 Register

The bit NVM_CONFIG1.FIXWS allows to switch between adaptive and fixed wait state configuration.

Attention: Any write operation to the register **CONFIG1** to switch between adaptive and fixed wait states configuration must only modify the bit **CONFIG1.FIXWS**. Changing other bits in **CONFIG1** can lead to unpredictable results.

CONFIG1

Configuration 1 Register

(4005 0048_H)

| Field | Bits | Type | Description |
|-------|-------|------|---|
| RES | 15:12 | rw | Reserved Must not be changed when programming the NVM_CONFIG1 register. |
| FIXWS | 11 | rw | Wait States Scheme Defines the scheme by which flash wait states are generated. With fixed wait states NVM_NVMCONF.WS defines the number of wait states. 0 _B adaptive wait states. 1 _B fixed wait states. |
| RES | 10:0 | rw | Reserved Must not be changed when programming the NVM_CONFIG1 register. |

8.10 Example Sequences

This section presents some low-level programming examples.

In all following operations the protection defined by **NVMCONF**.SECPROT needs to be taken into account.

8.10.1 Writing to Memory

8.10.1.1 Writing a Single Block

This sequence requires that the target block is already erased.

Additional assumption: **NVMPROG**.ACTION = 00_H.

1. Start a one-shot write operation:
Write **NVMPROG**.ACTION = 51_H or 91_H, respectively, if an automatic verification of the written data is to be performed or not.
2. Write data for one block to the physical address.
3. Poll flag **NVMSTATUS**.BUSY until write sequence has finished, or wait for NVMready interrupt (if enabled).
4. If an automatic verification of the written data was requested in the first step, read **NVMSTATUS**.VERR for the verification result.

If no verification of the written data was requested in step 1, and thus no read access to the NVM SFR is required in step 4, step 3 may be omitted.

The next access to the NVM module or the next write access to an NVM SFR (which ever comes first) will be automatically stalled, until the operation started in step 2 is finished.

8.10.1.2 Writing Blocks

This sequence requires the target blocks are already erased.

Additional assumption: **NVMPROG**.ACTION = 00_H.

1. Start a continuous write operation:
Write **NVMPROG**.ACTION = 61_H or A1_H, respectively, if an automatic verification of the written data is to be performed or not.
2. Write data for one block to the physical address.
3. Poll flag **NVMSTATUS**.BUSY until write sequence has finished, or wait for NVMready interrupt (if enabled).
Optionally, step 3 may be omitted: The next access to the NVM module or the next write access to an NVM SFR (which ever comes first) will be automatically stalled, until the operation started in step 2 is finished.
4. Jump to step 2 unless all data is written.

5. Stop continuous write operation:
Write **NVMPROG**.ACTION = 00_H.
6. If an automatic verification of the written data was requested in the first step, read **NVMSTATUS**.VERR for the verification result.

8.10.2 Erasing Memory

8.10.2.1 Erasing a Single Page

Assumption: **NVMPROG**.ACTION = 00_H.

1. Start a one-shot page erase operation:
Write **NVMPROG**.ACTION = 92_H.
2. Write dummy data for one word to one arbitrary word-aligned physical address of the page to be erased.
3. Poll flag **NVMSTATUS**.BUSY until page erase sequence has finished, or wait for NVMready interrupt (if enabled).

Optionally, step 3 may be omitted: The next access to the NVM module or the next write access to an NVM SFR (which ever comes first) will be automatically stalled, until the operation started in step 2 is finished.

8.10.2.2 Erasing Pages

Assumption: **NVMPROG**.ACTION = 00_H.

1. Start a continuous page erase operation:
Write **NVMPROG**.ACTION = A2_H.
2. Write dummy data for one word to one arbitrary word-aligned physical address of the page to be erased.
3. Poll flag **NVMSTATUS**.BUSY until page erase sequence has finished, or wait for NVMready interrupt (if enabled).

Optionally, step 3 may be omitted: The next access to the NVM module or the next write access to an NVM SFR (which ever comes first) will be automatically stalled, until the operation started in step 2 is finished.

4. Jump to step 2 unless all pages are erased.
5. Stop continuous page erase operation:
Write **NVMPROG**.ACTION = 00_H.

8.10.2.3 Erasing a Single Sector

Assumption: **NVMPROG**.ACTION = 00_H.

1. Start a one-shot sector erase operation:
Write **NVMPROG**.ACTION = 94_H.

2. Write dummy data for one word to one arbitrary word-aligned physical address of the sector to be erased.
3. Poll flag **NVMSTATUS.BUSY** until sector erase sequence has finished, or wait for NVMready interrupt (if enabled).
Optionally, step 3 may be omitted: The next access to the NVM module or the next write access to an NVM SFR (which ever comes first) will be automatically stalled, until the operation started in step 2 is finished.

8.10.2.4 Erasing Sectors

Assumption: **NVMPROG.ACTION** = 00_H.

1. Start a continuous sector erase operation:
Write **NVMPROG.ACTION** = A4_H.
2. Write dummy data for one word to one arbitrary word-aligned physical address of the sector to be erased.
3. Poll flag **NVMSTATUS.BUSY** until sector erase sequence has finished, or wait for NVMready interrupt (if enabled).
Optionally, step 3 may be omitted: The next access to the NVM module or the next write access to an NVM SFR (which ever comes first) will be automatically stalled, until the operation started in step 2 is finished.
4. Jump to step 2 unless all sectors are erased.
5. Stop continuous sector erase operation:
Write **NVMPROG.ACTION** = 00_H.

8.10.3 Verifying Memory

8.10.3.1 Verifying a Single Block

Assumption: **NVMPROG.ACTION** = 00_H.

1. Choose desired hardread level by setting NVMCONF.HRLEV.
2. Start a one-shot verify operation:
Write **NVMPROG.ACTION** = D0_H.
3. Write reference data for one block to the physical address.
4. Poll flag **NVMSTATUS.BUSY** until verify sequence has finished.
5. Read **NVMSTATUS.VERR** for the verification result.

8.10.3.2 Verifying Blocks

Assumption: **NVMPROG.ACTION** = 00_H.

1. Choose desired hardread level by setting NVMCONF.HRLEV.

2. Start a continuous verify operation:
Write **NVMPROG**.ACTION = E0_H.
3. Write reference data for one block to the physical address.
4. Poll flag **NVMSTATUS**.BUSY until verify sequence has finished.
Optionally, step 4 may be omitted: The next access to the NVM module or the next write access to an NVM SFR (which ever comes first) will be automatically stalled, until the operation started in step 3 is finished.
5. Jump to step 3 unless all blocks are verified.
6. Stop continuous verify operation:
Write **NVMPROG**.ACTION = 00_H.
7. Read **NVMSTATUS**.VERR for the verification result.

8.10.4 Writing to an Already Written Block

Normally, writing additional bits in an already written block is not feasible, since the already written ECC bits and the parity bits would need an update, too, which in most cases would require to erase some bits, which is not possible. The result would be an ECC-faulty block.

For special purposes a repeated update of specially constructed data is possible, e.g. to store some marker bits for use in a power loss recovery SW implementation.

Starting with an erased block, and making use of the special structure of the ECC, it is possible to repeatedly add two newly written bits in identical bit positions to two arbitrary words of the block. This principle is shown in the exemplary writing scheme of **Table 8-4**, where a block is updated 32 times without corruption of the ECC, i.e. the data stays ECC protected throughout the procedure.

Table 8-4 Incremental Update of a Block with Specially Constructed Data

| Operation | Block Write Data | Resulting Block Content ¹⁾ |
|---------------------------|---|---|
| Erase block | | FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF |
| Add 1 st value | FFFFFFFF FFFFFFFC FFFFFFFF FFFFFFFC | FFFFFFFF FFFFFFFC FFFFFFFF FFFFFFFC |
| Add 2 nd value | FFFFFFFF FFFFFFF3 FFFFFFFF FFFFFFF3 | FFFFFFFF FFFFFFF0 FFFFFFFF FFFFFFF0 |
| Add 3 rd value | FFFFFFFF FFFFFFFCF FFFFFFFF FFFFFFCF | FFFFFFFF FFFFFFFC0 FFFFFFFF FFFFFFC0 |
| Add 4 th value | FFFFFFFF FFFFFFF3F FFFFFFFF FFFFFF3F | FFFFFFFF FFFFFFF00 FFFFFFFF FFFFFF00 |

Table 8-4 Incremental Update of a Block with Specially Constructed Data

| Operation | Block Write Data | Resulting Block Content ¹⁾ |
|--|--|---------------------------------------|
| Add 5 th value | FFFFFFFF FFFFCFF FFFFFFFF FFFCFF | FFFFFFFF FFFFC00 FFFFFFFF FFFC00 |
| Add 6 th value | FFFFFFFF FFFF3FF FFFFFFFF FFF3FF | FFFFFFFF FFFF000 FFFFFFFF FFF000 |

| 32 nd value | 3FFFFFFF FFFFFFFF 3FFFFFFF FFFFFFF | 00000000 0000000 00000000 0000000 |
| Add to invalidate written values ²⁾ | FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFE | Same as before, but ECC2-faulty |

1) ECC-clean and parity-clean (ECC bits and parity bits all stay erased), except where indicated otherwise.

2) This write data can be written on any of the states above (except the completely erased state), always resulting in an unchanged data content, but now with an ECC2 error (three ECC bits and one parity bit are written).

Other combinations of write values are possible, too, as long as the basic “add two identical bits in each of two words” is adhered to. In **Table 8-4** it is also shown that an invalidation of the data by deliberately creating an ECC2 error is possible.

To minimize the write times and also to minimize the cycle load of the block, it is important to only write the new bits of the block as shown in **Table 8-4**. In principle it is possible to repeatedly write also the already written bits again, but this would unnecessarily increase the writing times and would also increase the cycle load.

8.10.5 Sleep Mode

Assumption: Active mode (**NVMSTATUS.SLEEP** = 0_B) and **NVMSTATUS.BUSY** = 0_B.

To Enter Sleep Mode

1. Execute WFE/WFI or **NVMCONF.NVM_ON** = 0_B.
2. **NVMSTATUS.BUSY** = 1_B and **NVMSTATUS.SLEEP** = 1_B until sleep mode is reached.
3. **NVMSTATUS.BUSY** = 0_B and **NVMSTATUS.SLEEP** = 1_B while in sleep mode.

To Wake-up from Sleep Mode

1. Any wake-up event and **NVMCONF.NVM_ON** = 1_B.
2. **NVMSTATUS.BUSY** = 1_B and **NVMSTATUS.SLEEP** = 1_B until active mode is reached.
3. Poll flag **NVMSTATUS.BUSY** until wake-up sequence has finished, or wait for NVMready interrupt (if enabled).
4. **NVMSTATUS.BUSY** = 0_B and **NVMSTATUS.SLEEP** = 0_B while in active mode.

A wake-up event while the goto sleep sequence has not finished yet, does not shorten this sequence, but only directly starts the wake-up sequence afterwards.

8.10.6 Timing

This state diagram shows the transitions and timings of all possible sequences.

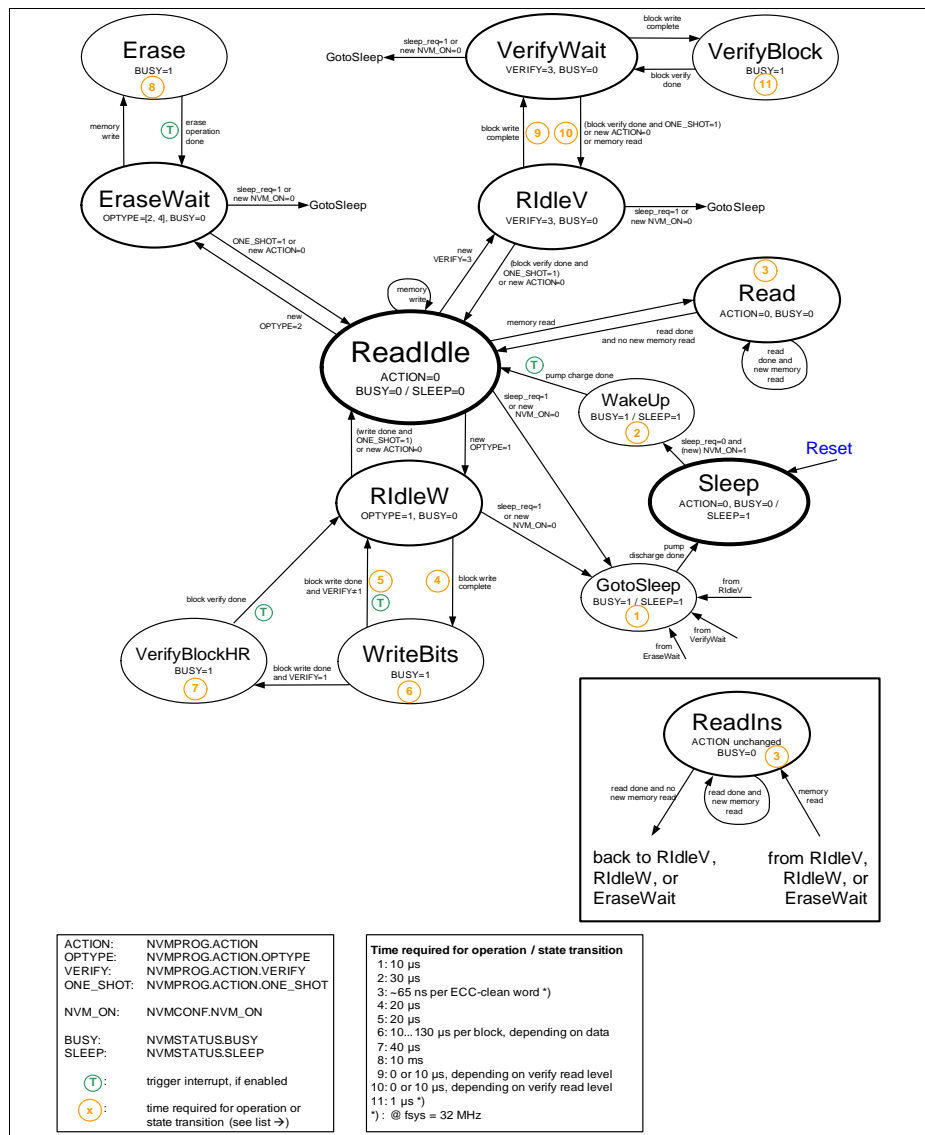

Figure 8-4 State Diagram of the NVM Module Timings are preliminary

9 Peripheral Access Unit (PAU)

This chapter describes Peripheral Access Unit (PAU) in XMC1100.

9.1 Overview

The PAU supports access control of memories and peripherals in a central place.

9.1.1 Features

The PAU provides the following features:

- Allows user application to enable/disable the access to the registers of a peripheral
- Generates a HardFault exception when there is an access to a disabled or unassigned address location
- Provides information on availability of peripherals and size of memories

9.2 Peripheral Privilege Access Control

The user application can use the Peripheral Privilege Access Registers, PRIVDISn, to disable access to a peripheral. When the PDISx bit corresponding to the peripheral is set, the memory address space mapped to the peripheral is rendered invalid. An access to such an invalid address causes a HardFault exception.

The application can clear the same bit to enable accesses to the peripheral again.

Table 9-1 shows the peripherals and their assigned PDISx bits. Peripherals without a PDISx bit are accessible at all times.

Table 9-1 Peripherals Availability and Privilege Access Control

| Peripheral | Address Grouping | AVAILn.AVAILx bit | PRIVDIS.PDISx bit |
|------------|------------------|-------------------|-------------------|
| Flash | Flash SFRs | - | PRIVDIS0.2 |
| SRAM | RAM Block 1 | AVAIL0.5 | PRIVDIS0.5 |
| | RAM Block 2 | AVAIL0.6 | PRIVDIS0.6 |
| | RAM Block 3 | AVAIL0.7 | PRIVDIS0.7 |
| WDT | WDT | - | PRIVDIS0.19 |
| Ports | Port 0 | AVAIL0.22 | PRIVDIS0.22 |

| | USIC0_CH1 | AVAIL1.1 | PRIVDIS1.1 |
| PRNG | PRNG | AVAIL1.4 | - |

Peripheral Access Unit (PAU)

Table 9-1 Peripherals Availability and Privilege Access Control

| Peripheral | Address Grouping | AVAILn.AVAILx bit | PRIVDIS.PDISx bit |
|------------|----------------------------|-------------------|-------------------|
| VADC0 | VADC0 Basic SFRs | AVAIL1.5 | PRIVDIS1.5 |
| SHS0 | SHS0 | AVAIL1.8 | PRIVDIS1.8 |
| CCU4 | CC40 and CCU40 Kernel SFRs | AVAIL1.9 | PRIVDIS1.9 |
| | CC41 | AVAIL1.10 | PRIVDIS1.10 |
| | CC42 | AVAIL1.11 | PRIVDIS1.11 |
| | CC43 | AVAIL1.12 | PRIVDIS1.12 |

9.3 Peripheral Availability and Memory Size

The availability of peripherals and memory sizes varies according to product variants. The user application can read the Peripheral Availability Registers, AVAILn, to check for the availability of peripherals in a product variant. Refer to [Table 9-1](#) for the bit assignment. Similarly, the Memory Size Registers (e.g. FLSIZE for Flash memory) can be used to check for the size of the available memories.

9.4 Service Request Generation

The PAU generates a hard fault exception when there is an access to an invalid address.

9.5 Debug Behaviour

The PAU does not support a suspend mode while the system is halted by the debugger. That means that the PAU continues its operation during debug halt.

9.6 Power, Reset and Clock

The PAU is located in the core power domain. The module can be reset to its default state by a system reset.

The PAU module is clocked by the main clock, MCLK, from SCU

9.7 Initialization and System Dependencies

The PAU is always available after reset.

9.8 PAU Registers

Registers Overview

The absolute register address is calculated by adding:

Peripheral Access Unit (PAU)

Module Base Address + Offset Address

Table 9-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| PAU | 4000 0000 _H | 4000 FFFF _H | |

On-chip Peripherals

10 Window Watchdog Timer (WDT)

Purpose of the Window Watchdog Timer module is improvement of system integrity. WDT triggers the system reset or other corrective action like e.g. an interrupt if the main program, due to some fault condition, neglects to regularly service the watchdog (also referred to as “kicking the dog”, “petting the dog”, “feeding the watchdog” or “waking the watchdog”). The intention is to bring the system back from the unresponsive state into normal operation.

References

[6] Cortex-M0 User Guide, ARM DUI 0467B (ID081709)

10.1 Overview

A successful servicing of the WDT results in a pulse on the signal `wdt_service`. The signal is offered also as an alternate function output can be used to show to an external watchdog that the system is alive.

The WDT timer is a 32-bit counter, which counts up from 0_H . It can be serviced while the counter value is within the window boundary, i.e. between the lower and the upper boundary value. Correct servicing results in a reset of the counter to 0_H . A so called “Bad Service” attempt results in the system reset request.

The timer block is running on the f_{WDT} clock which is independent from the bus clock. The timer value is updated in the corresponding AHB register **TIM**. This mechanism enables immediate response on a read access from the bus.

10.1.1 Features

The watchdog timer (WDT) is an independent window watchdog timer.

The features are:

- Triggers system reset when not serviced on time or serviced in a wrong way
- Servicing restricted to be within boundaries of refresh window
- Can run from an independent clock
- Provides service indication to an external pin
- Can be suspended in halting mode
- Provides optional pre-warning alarm before reset

Window Watchdog Timer (WDT)

Table 10-1 Application Features

| Feature | Purpose/Application |
|--|---|
| System reset upon Bad Servicing | Triggered to restore system stable operation and ensure system integrity |
| Servicing restricted to be within defined boundaries of refresh window | Allows to consider minimum and maximum software timing |
| Independent clocks | To ensure that WDT counts even in case of the system clock failure |
| Service indication on external pin | For dual-channel watchdog solution, additional external control of system integrity |
| Suspending in HALT mode | Enables safe debugging with productive code |
| Pre-warning alarm | Software recovery to allow corrective action via software recovery routine bringing system back from the unresponsive state into normal operation |

10.1.2 Block Diagram

The WDT block diagram is shown in [Figure 10-1](#).

Figure 10-1 Watchdog Timer Block Diagram

10.2 Time-Out Mode

An overflow results in an immediate reset request going to the RCU of the SCU via the signal `wdt_rst_req` whenever the counter crosses the upper boundary it triggers an overflow event pre-warning is not enabled with **CTR** register. A successful servicing performed with writing a unique value, referred to as “Magic Word” to the **SRV** register of the WDT within the valid servicing window, results in a pulse on the signal `wdt_service` and reset of the timer counter.

Figure 10-2 Reset without pre-warning

The example scenario depicted in **Figure 10-2** shows two consecutive service pulses generated from WDT module as the result of successful servicing within valid time windows. The situation where no service has been performed immediately triggers generation of reset request on the `wdt_rst_req` output after the counter value has exceeded window upper bound value.

10.3 Pre-warning Mode

While in pre-warning mode the effect of the overflow event is different with and without pre-warning enabled. The first crossing of the upper bound triggers the outgoing alarm signal `wdt_alarm` when pre-warning is enabled. Only the next overflow results a reset request. The alarm status is shown via register **WDTSTS** and can be cleared via register **WDTCLR**. A clear of the alarm status will bring the WDT back to normal state.

Window Watchdog Timer (WDT)

Figure 10-3 Reset after pre-warning

The example scenario depicted in [Figure 10-3](#) shows service pulse generated from WDT module as the result of successful servicing within valid time window. WDT generates alarm pulse on `wdt_alarm` upon first missing servicing. The alarm signal is routed as interrupt request to the SCU. Within this alarm service request the user can clear the WDT status bit and give a proper WDT service before it overflows next time. Otherwise WDT generates reset request on `wdt_rstn` upon the second missing service.

10.4 Bad Service Operation

A bad service attempt results in a reset request. A bad service attempt can be due to servicing outside the window boundaries or servicing with an invalid Magic Word.

Window Watchdog Timer (WDT)

Figure 10-4 Reset upon servicing in a wrong window

The example in [Figure 10-4](#) shows servicing performed outside of valid servicing window. Attempt to service WDT while counter value remains below the window lower bound results in immediate reset request on wdt_rst_req signal.

Figure 10-5 Reset upon servicing with a wrong magic word

Window Watchdog Timer (WDT)

The example in [Figure 10-5](#) shows servicing performed within a valid servicing window but with an invalid Magic Word. Attempt to write a wrong word to the [SRV](#) register results in immediate reset request on wdt_rst_req signal.

10.5 Service Request Processing

The WDT generates watchdog alarm service requests via wdt_alarm output signal upon first counter overflow over watchdog upper bound when pre-warning mode is enabled. The alarm service request is serviced in SCU.

Service requests can be disabled respectively by service request mask register in SCU.

10.6 Debug Behavior

The WDT function can be suspended when the CPU enters HALT mode. WDT debug function is controlled with DSP bit field in [CTR](#) register and it is set to be suspended by default.

10.7 Power, Reset and Clock

The WDT module is a part of the core domain and supplied with V_{DDC} voltage.

All WDT registers get reset with the system reset.

A sticky bit in the Reset Status Register, RSTSTAT, of SCU/RCU module indicates whether the last system reset has been triggered by the WDT module. This bit does not get reset with system reset.

The input clock of the WDT counter is provided by the internal 32kHz standby clock from SCU/CCU module, independently from the AHB interface clock.

The WDT module clock is default disabled and can be enabled via the SCU_CGATCLR0 register. Enabling and disabling the module clock could cause load change and clock blanking could happen as explained in the CCU (Clock Gating Control) section of the SCU chapter. It is strongly recommended to setup the module clock in the user initialisation code to avoid clock blanking during runtime.

10.8 Initialization and Control Sequence

Programming model of the WDT module assumes several scenarios where different control sequences apply.

Note: Some of the scenarios described in this chapter require operations on system level that are not in the scope of the WDT module description, therefore for detailed information please refer to relevant chapters of this document.

10.8.1 Initialization & Start of Operation

Complete WDT module initialization is required upon system reset.

Window Watchdog Timer (WDT)

- check reason for last system reset in order to determine power state
 - read out SCU_RSTSTAT.RSTSTAT register bit field to determine last system reset cause and clear this bit using bit SCU_RSTCLR.RSCLR
 - perform appropriate operations dependent on the last system reset cause
- WDT software initialization sequence
 - enable WDT clock with SCU_CGATCLR0.WDT register bit field
 - set lower window bound with WDT_WLB register
 - set upper window bound with WDT_WUB register
 - configure external watchdog service indication (optional, please refer to PORT chapter)
 - enable interrupt for pre-warning alarm on system level with SCU_SRMSK register (optional, used in WDT pre-warning mode only)
- software start sequence
 - select mode (Time-Out or Pre-warning) and enable WDT module with WDT_CTR register
- service the watchdog
 - write magic word to WDT_SRV register within valid time window

10.8.2 Software Stop & Resume Operation

The WDT module can be stopped and re-started at any point of time for e.g. debug purpose using software sequence.

- software stop sequence
 - disable WDT module with WDT_CTR register
- perform any user operations
- software start (resume) sequence
 - enable WDT module with WDT_CTR register with WDT_CTR register
- service the watchdog
 - write magic word to WDT_SRV register within valid time window

10.8.3 Enter Sleep/Deep-Sleep & Resume Operation

The WDT counter clock can be configured to stop while in sleep or deep-sleep mode. No direct software interaction with the WDT is required in those modes and no watchdog time-out will fire if the WDT clock is configured to stop while CPU is sleeping.

- software configuration sequence for sleep/deep-sleep mode
 - configure WDT behavior with SCU_CGATx register
- enter sleep/deep-sleep mode software sequence

Window Watchdog Timer (WDT)

- select sleep or deep-sleep mode in CPU (for details please refer to Cortex-M0 documentation [6])
- enter selected mode (for details please refer to Cortex-M0 documentation [6])
- wait for a wake-up event (no software interaction, CPU stopped)
- resume operation (CPU clock restarted automatically on an event)
- service the watchdog
 - write magic word to WDT_SRV register within valid time window

10.8.4 Pre-warning Alarm Handling

The WDT will fire pre-warning alarm before requesting system reset while in pre-warning mode and not serviced within valid time window. The WDT status register indicating alarm must be cleared before the timer counter value crosses the upper bound for the second time after firing the alarm. After clearing of the alarm status regular watchdog servicing must be performed within valid time window.

- alarm event
 - exception routine (service request) clearing WDT_WDTSTAT register with WDT_WDTCLR register
- service the watchdog
 - write magic word to WDT_SRV register within valid time window

Window Watchdog Timer (WDT)

10.9 WDT Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 10-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|--------------------------|
| WDT | 4002 0000 _H | 4002 FFFF _H | Watchdog Timer Registers |

Table 10-3 Register Overview

| Short Name | Description | Offset Addr. | Access Mode | | Description See |
|----------------------|--------------------------------|-----------------|-------------|-------|----------------------------|

10.9.1 Registers Description

ID

The module unique ID register.

Window Watchdog Timer (WDT)

ID

WDT Module ID Register

(0000_H)

Reset Value: 00AD C0XX_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Number Indicates the revision number of the implementation. The value of a module revision starts with 01 _H (first revision). |
| MOD_TYPE | [15:8] | r | Module Type This bit field is fixed to C0 _H . |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines the module identification number. |

CTR

The operation mode control register.

Window Watchdog Timer (WDT)

CTR

WDT Control Register

(04_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|-----------------------------|------|--|
| ENB | 0 | rw | Enable 0 _B disables watchdog timer, 1 _B enables watchdog timer |
| PRE | 1 | rw | Pre-warning 0 _B disables pre-warning 1 _B enables pre-warning, |
| DSP | 4 | rw | Debug Suspend 0 _B watchdog timer is stopped during debug halting mode 1 _B watchdog timer is not stopped during debug halting mode |
| SPW | [15:8] | rw | Service Indication Pulse Width Pulse width (SPW+1) of service indication in f _{WDT} cycles |
| 0 | [3:2], [7:5], [31:16] | r | reserved |

SRV

The WDT service register. Software must write a magic word while the timer value is within the valid window boundary. Writing the magic word while the timer value is within the window boundary will service the watchdog and result a reload of the timer with 0H.

Window Watchdog Timer (WDT)

Upon writing data different than the magic word within valid time window or writing even correct Magic Word but outside of the valid time window no servicing will be performed. Instead will request an immediate system reset request.

SRV

WDT Service Register

(08_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| SRV | [31:0] | w | Service Writing the magic word ABADCAFE _H while the timer value is within the window boundary will service the watchdog. |

Window Watchdog Timer (WDT)

TIM

The actual watchdog timer register count value. This register can be read by software in order to determine current position in the WDT time window.

TIM

WDT Timer Register

(0C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TIM | [31:0] | rh | Timer Value Actual value of watchdog timer value. |

WLB

The Window Lower Bound register defines the lower bound for servicing window. Servicing of the watchdog has only effect within the window boundary

WLB

WDT Window Lower Bound Register (10_H)

Reset Value: 0000 0000_H

Window Watchdog Timer (WDT)

WDTSTS

WDT Status Register

(0018_H)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

10.10 Interconnects

Table 10-4 Pin Table

| Input/Output | I/O | Connected To | Description |
|------------------------------|-----|--------------|---|
| Clock and Reset Signals | | | |
| f_{WDT} | I | SCU.CCU | timer clock |
| Timer Signals | | | |
| wdt_service | O | PORTS | service indication to external watchdog |
| HALTED | I | CPU | In halting mode debug. HALTED remains asserted while the core is in debug. |
| Service Request Connectivity | | | |
| wdt_alarm | O | SCU.GCU | pre-warning alarm |
| wdt_rst_req | O | SCU.RCU | reset request |

11 Real Time Clock (RTC)

Real-time clock (RTC) is a clock that keeps track of the current time. RTCs are present in almost any electronic device which needs to keep accurate time in a digital format for clock displays and computer systems.

11.1 Overview

The RTC module tracks time with separate registers for hours, minutes, and seconds. The calendar registers track date, day of the week, month and year with automatic leap year correction¹⁾. The clock of RTC is selectable via bit SCU_CLKCR.RTCLKSEL.

The timer may remains operational during sleep or deep sleep mode.

11.1.1 Features

The features of the Real Time Clock (RTC) module are:

- Real time keeping with
 - 32.768 kHz internal clock
- Periodic time-based interrupt
- Programmable alarm interrupt on time match
- Supports wake-up mechanism from sleep or deep sleep mode

Table 11-1 Application Features

| Feature | Purpose/Application |
|--|--|
| Precise real time keeping | Reduced need for time adjustments |
| Periodic time-based interrupt | Scheduling of operations performed on precisely defined intervals |
| Programmable alarm interrupt on time match | Scheduling of operations performed on precisely defined times |
| Supports wake-up mechanism from sleep or deep sleep mode | Autonomous wakeups from sleep or deep sleep mode for system state control and maintenance routine operations |

11.1.2 Block Diagram

The RTC block diagram is shown in [Figure 11-1](#).

The main building blocks of the RTC is Time Counter implementing real time counter and RTC Registers containing multi-field registers for the time counter and alarm

¹⁾ The automatic leap year correction is performed when the year is divisible by 4.

Real Time Clock (RTC)

programming register where dedicated fields represent a separate values for elapsing second, minutes, hours, days, days of week, months and years.

The RTC module is controlled directly from SCU module and shares system bus interface with other sub-modules of SCU.

Access to the RTC registers is performed via Register Mirror updated over serial interface.

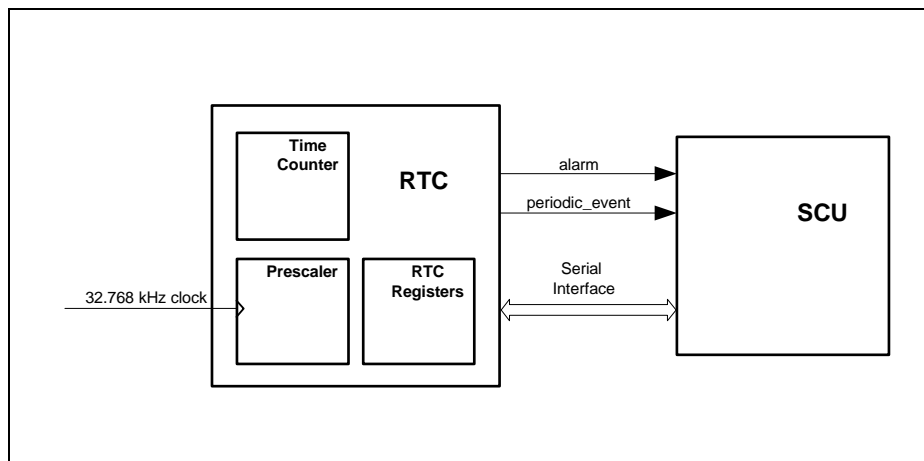

Figure 11-1 Real Time Clock Block Diagram Structure

11.2 RTC Operation

The RTC timer counts seconds, minutes, hours, days, days of week, months and years the time in separate fields (see [Figure 11-2](#)). Individual bit fields of the RTC counter can be programmed and read with software over serial interface via mirror registers in SCU module.

Figure 11-2 Block Diagram of RTC Time Counter

Occurrence of an internal timer event is stored in the service request raw status register **RAWSTAT**. The values of the status register **RAWSTAT** drive the outgoing service request lines alarm and periodic_event.

11.3 Register Access Operations

The RTC module is a part of SCU from programming model perspective and shares register address space for configuration with other sub-modules of SCU. RTC registers are instantiated in the RTC module and mirrored in SCU. The registers get updated in both clock domains over serial interface running at 32kHz clock rate.

Any update of the registers is performed with some delay required for data to propagate to and from the mirror registers over serial interface. Accesses to the RTC registers in core domain must not block the bus interface of SCU module. For details of the register mirror and serial communication handling please refer to SCU chapter.

For consistent write to the timer registers **TIMO** and **TIM1**, the register **TIMO** has to be written before the register **TIM1**. Transfer of the new values from the register mirror starts only after both registers have been written.

Real Time Clock (RTC)

For consistent read-out of the timer registers **TIMO** and **TIM1**, the register **TIMO** has to be read before the register **TIM1**. The value of **TIM1** is stored in a shadow register upon each read of **TIMO** before they get copied to the mirror register in core domain.

11.4 Service Request Processing

The RTC generates service requests upon:

- periodic timer events
- configured alarm condition

The service requests can be processed in the core domain as regular service requests or as wake-up triggers from sleep or deep sleep mode.

11.4.1 Periodic Service Request

The periodic timer service request is raised whenever a non-masked field of the timer counter gets updated. Masking of the bits is performed using **MSKSR** register. Periodic Service requests can be disabled with **MSKSR**.

11.4.2 Timer Alarm Service Request

The alarm interrupt is triggered when **TIMO** and **TIM1** bit fields values match all corresponding bit fields values of **ATIMO**, **ATIM1** registers. The Timer Alarm Service requests can be enabled/disabled with the **MSKSR** register .

11.5 Debug Behavior

The RTC function can be suspended when the CPU enters HALT mode. RTC debug function is controlled with SUS bit field in **CTR** register.

Note: In XMC1100, bit CTR.SUS is reset to its default value by any reset. Hence, if suspend function is required during debugging, it is recommended to enable the debug suspend function in the user initialisation code. Before programming the register, the module clock has to be enabled and special care need to be handled while enabling the module clock as described in the CCU (Clock Gating Control) section of the SCU chapter.

11.6 Power, Reset and Clock

RTC can be programmed to remains powered up in sleep and deep sleep mode.

The RTC module remains in reset state after initial power up until reset released.

The RTC timer is running from an internal 32.768 kHz clock. The prescaler setting of $7FFF_H$ results in an once per second update of the RTC timer.

The RTC module clock is default disabled and can be enabled via the SCU_CGATCLR0 register.

11.7 Initialization and Control Sequence

Programming model of the RTC module assumes several scenarios where different control sequences apply.

Note: Some of the scenarios described in this chapter require operations on system level that are not in the scope of the RTC module description, therefore for detailed information please refer to relevant chapters of this document.

11.7.1 Initialization & Start of Operation

Complete RTC module initialization is required upon reset. Accesses to RTC registers are performed via dedicated mirror registers (for more details please refer to SCU chapter)

- enable the clock to RTC module
 - write one to SCU_CGATCLR0.RTC
- program RTC_TIM0 and RTC_TIM1 registers with current time
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_TIM0 and RTC_TIM1 registers
 - write a new value to the RTC_TIM0 and RTC_TIM1 registers
- enable RTC module to start counting time
 - write one to RTC_CTR.ENB

Note: To ensure a successful transfer over serial interface, RTC_TIM0 and RTC_TIM1 can only be written once for each transfer. In addition, these registers must be written in 32-bit data width. Individual bit access will not start the serial transfer operation.

11.7.2 Configure and Enable Periodic Event

The RTC periodic event configuration requires programming in order to enable interrupt request generation out upon a change of value in the corresponding bit fields.

- enable service request for periodic timer events in RTC module
 - set respective bit field (MPSE, MPMI, MPHO, MPDA, MPMO, MPYE) in RTC_MSKSR register to enable the individual periodic timer events

11.7.3 Configure and Enable Timer Event

The RTC alarm event configuration requires programming in order to enable interrupt request generation out upon compare match of values in the corresponding bit fields of TIM0 and TIM1 against ATIM0 and ATIM1 respectively.

- program compare values in individual bit fields of ATIM0 and ATIM1 in RTC module
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_ATIM0 and RTC_ATIM1 registers
 - write to RTC_ATIM0 and RTC_ATIM1 registers

Real Time Clock (RTC)

- enable service request for timer alarm events in RTC module
 - set MAI bit field of RTC_MSKSR register in order enable individual periodic timer events

Note: To ensure a successful transfer over serial interface, RTC_ATIM0 and RTC_ATIM1 can only be written once for each transfer. In addition, these registers must be written in 32-bit data width. Individual bit access will not start the serial transfer operation.

11.8 RTC Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 11-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| RTC | 4001 0A00 _H | 4001 0AFF _H | |

11.8.1 Registers Description

ID

Read-only ID register of the RTC module containing unique identification code of the RTC module.

ID

RTC Module ID Register

(00_H)

Reset Value: 00A3 C0XX_H

| Field | Bits | Type | Description |
|-------------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Number Indicates the revision number of the implementation. The value of a module revision starts with 01 _H (first revision). |
| MOD_TYPE | [15:8] | r | Module Type This bit field is fixed to C0 _H . |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines the module identification number. |

Real Time Clock (RTC)

CTR

RTC Control Register providing control means of the operation mode of the module.

CTR

RTC Control Register

(04_H)

Reset Value: 7FFF 0000_H

| | | | | | | | | | | | | | | | |
|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| SUS | 1 | rw | Debug Suspend Control 0 _B RTC is not stopped during halting mode debug 1 _B RTC is stopped during halting mode debug |
| DIV | [31:16] | rw | Divider Value reload value of RTC prescaler. Clock is divided by DIV+1. 7FFF _H is default value for RTC mode with 32.768 kHz clock |
| 0 | [15:2] | r | Reserved Read as 0; should be written with 0 |

RAWSTAT

RTC Raw Service Request Register contains raw status info i.e. before status mask takes effect on generation of service requests or interrupts. This register serves debug purpose but can be also used for polling of the status without generating service requests.

RAWSTAT

RTC Raw Service Request Register (08_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|-----------------|------|--|
| RPSE | 0 | rh | Raw Periodic Seconds Service Request Set whenever seconds count increments |
| RPMI | 1 | rh | Raw Periodic Minutes Service Request Set whenever minutes count increments |
| RPHO | 2 | rh | Raw Periodic Hours Service Request Set whenever hours count increments |
| RPDA | 3 | rh | Raw Periodic Days Service Request Set whenever days count increments |
| RPMO | 5 | rh | Raw Periodic Months Service Request Set whenever months count increments |
| RPYE | 6 | rh | Raw Periodic Years Service Request Set whenever years count increments |
| RAI | 8 | rh | Alarm Service Request Set whenever count value matches compare value |
| 0 | 4, 7, [31:9] | r | Reserved |

STSSR

RTC Service Request Status Register contains status info reflecting status mask effect on generation of service requests or interrupts. This register needs to be accessed by software in order to determine the actual cause of an event.

STSSR

RTC Service Request Status Register (0C_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|-----|----|----------|----------|----|----------|----------|----------|

| 0 | 4, 7, [31:9] | r | Reserved |

Real Time Clock (RTC)
CLRSR

RTC Clear Service Request Register serves purpose of clearing sticky bits of **RAWSTAT** and **STSSR** registers. Write one to a bit in order to clear the status bit. Writing zero has no effect on the set nor reset bits.

CLRSR
RTC Clear Service Request Register (14_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|------|------|--|
| RPSE | 0 | w | Raw Periodic Seconds Interrupt Clear 0 _B no effect 1 _B clear status bit |

| RAI | 8 | w | Raw Alarm Interrupt Clear 0 _B no effect 1 _B clear status bit |
| 0 | 4, 7, [31:9] | r | Reserved |

ATIM0

RTC Alarm Time Register 0 serves purpose of programming single alarm time at a desired point of time reflecting comparison against **TIMO** register. The ATIM0 register contains portion of bit fields for seconds, minutes, hours and days. Upon attempts to write an invalid value to a bit field e.g. exceeding maximum value a default value gets programmed as described for each individual bit fields.

ATIM0

RTC Alarm Time Register 0 (18_H) **Reset Value: 0000 0000_H**

|------------|--------|------|---|
| ASE | [5:0] | rw | Alarm Seconds Compare Value Match of seconds timer count to this value triggers alarm seconds interrupt. Setting value equal or above 3C _H results in setting the field value to 0 _H |
| AMI | [13:8] | rw | Alarm Minutes Compare Value Match of minutes timer count to this value triggers alarm minutes interrupt. Setting value equal or above 3C _H results in setting the field value to 0 _H |

Real Time Clock (RTC)

| Field | Bits | Type | Description |
|------------|---|------|---|
| AHO | [20:16] | rw | Alarm Hours Compare Value Match of hours timer count to this value triggers alarm hours interrupt. Setting value equal or above 18 _H results in setting the field value to 0 _H |
| ADA | [28:24] | rw | Alarm Days Compare Value Match of days timer count to this value triggers alarm days interrupt. Setting value equal or above 1F _H results in setting the field value to 0 _H |
| 0 | [7:6], [15:14], [23:21], [31:29] | r | Reserved |

ATIM1

RTC Alarm Time Register 1 serves purpose of programming single alarm time at a desired point of time reflecting comparison against **TIM1** register. The ATIM1 register contains portion of bit fields for months and years. Upon attempts to write an invalid value to a bit field e.g. exceeding maximum value a default value gets programmed as described for each individual bit fields.

ATIM1

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|-------------------|------|---|
| AMO | [11:8] | rw | Alarm Month Compare Value Match of months timer count to this value triggers alarm month interrupt. Setting value equal or above the number of days of the actual month count results in setting the field value to 0 _H |
| AYE | [31:16] | rw | Alarm Year Compare Value Match of years timer count to this value triggers alarm years interrupt. |
| 0 | [7:0], [15:12] | r | Reserved |

TIM0

RTC Time Register 0 contains current time value for seconds, minutes, hours and days. The bit fields get updated in intervals corresponding with their meaning accordingly. The register needs to be programmed to reflect actual time after initial power up and will continue counting time also while in sleep or deep sleep mode if enabled. Upon attempts to write an invalid value to a bit field e.g. exceeding maximum value a default value gets programmed as described for each individual bit fields.

12 System Control Unit (SCU)

The SCU is the SoC power, reset and a clock manager with additional responsibility of providing system stability protection and other auxiliary functions.

12.1 Overview

The functionality of the SCU described in this chapter is organized in the following sub-chapters, representing different aspects of system control:

- Miscellaneous control functions, GCU [Chapter 12.2](#)
- Power control, PCU [Chapter 12.3](#)
- Reset operation, RCU [Chapter 12.4](#)
- Clock Control, CCU [Chapter 12.5](#)

12.1.1 Features

The following features are provided for monitoring and controlling the system:

- General Control
 - Start-up Software (SSW) and Boot Mode Support
 - Memory Content Protection
 - Interrupt Handling
- Power control
 - On-chip core supply generation via EVR
 - Power Validation
 - Supply Watchdog
 - Voltage Monitoring
 - Load Change Handling
- Reset Control
 - Reset assertion on various reset request sources
 - System Reset Generation
 - Inspection of reset sources after reset
- Clock Control
 - Clock Generation
 - Clock Supervision
 - Individual Peripheral Clock Gating
 - Clock Blanking Support

12.1.2 Block Diagram

Figure 12-1 shows the following sub-units:

- Power Control Unit (PCU)
- Reset Control Unit (RCU)
- Clock Control Unit (CCU)
- General Control Unit (GCU)

All the SFRs in SCU module are accessible via the AHB and the 16-bit APB bus interface as shown in **Figure 12-1**. The APB bus interface is used to access the group of SFR called ANACTRL register. These registers are used to configure the analog modules in the system, namely, the embedded voltage regulator (EVR) and the digitally controlled oscillators (DCO1 and DCO2). The other group of SFR called SCU register are accessible via the AHB bus interface.

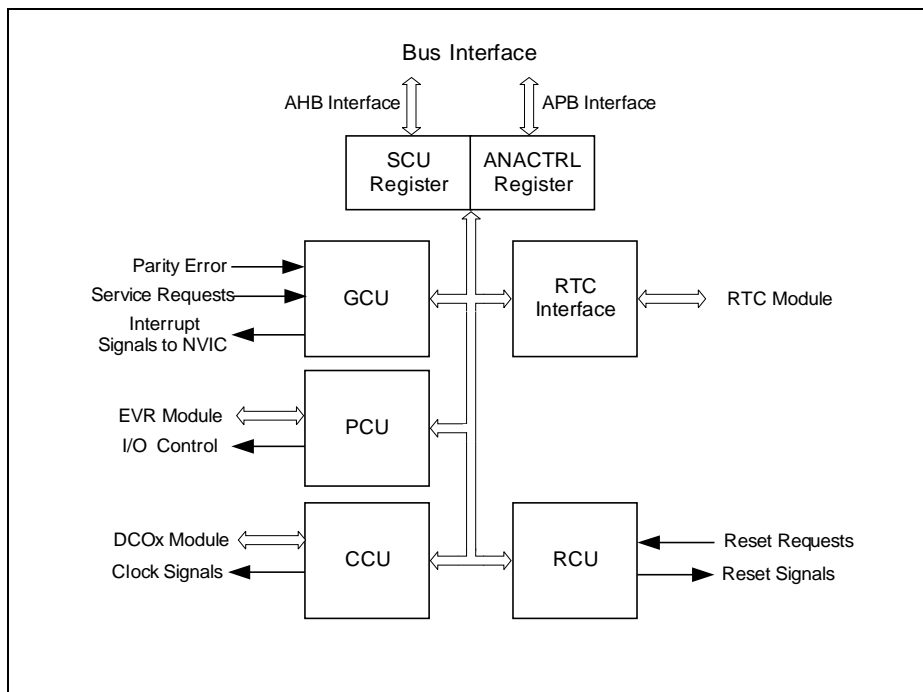

Figure 12-1 SCU Block Diagram

System Control Unit (SCU)**Interface of General Control Unit**

The General Control Unit GCU has a memory fault interface to the memory validation logic of each on-chip SRAM and the Flash to receive memory fault events, as parity errors.

Interface of Power Control Unit

The Power Control Unit PCU has an interface to the Embedded Voltage Regulator (EVR) and an interface to the CCU module. The PCU related signals are described in more detail in [Chapter 12.3](#).

Interface of Reset Control Unit

The Reset Control Unit RCU has an interface to the Embedded Voltage Regulator (EVR). The RCU receives the power-on reset and the brownout reset information from the EVR. Reset requests are coming to the unit from the watchdog, the CPU, the GCU and the clock control unit (CCU). The RCU is providing the reset signals to all other units of the chip in the core power domain. The RCU related signals are described in more detail in [Chapter 12.4](#).

Interface of Clock Control Unit

The Clock Control Unit (CCU) receives the clock source from the on-chip Digitally Controlled Oscillator (DCO). The CCU provides the clock signals to all other units of the chip.

Interface of RTC

Access to the RTC module is served over a serial interface. The interface provides mirror registers updated via the serial interface to the RTC module registers. Update of the mirror registers over the serial is controlled using **MIRRSTS** registers. End of update can also trigger service requests via **SRRAW** register. Refresh of the registers in the register mirror are performed continuously, as fast as possible in order to instantly reflect any register state change on both sides.

The RTC module functionality is described in separate RTC chapter.

12.2 Miscellaneous Control Functions (GCU)

System Control implements system management functions accessible via GCU registers. General system control including various auxiliary function is performed in the General Control Unit (GCU).

12.2.1 Service Requests Handling

Service request events listed in [Table 12-1](#) can result in assertion of an interrupt. Please refer to [SRMSK](#) a register description.

The interrupt structure is shown in [Figure 12-2](#). The interrupt request or the corresponding interrupt set bit (in register [SRSET](#)) can trigger the interrupt generation at the selected interrupt node x. The service request pulse is generated independently from the interrupt flag in register [SRRAW](#). The interrupt flag can be cleared by software by writing to the corresponding bit in register [SRCLR](#).

Figure 12-2 Service Request Handling

The flag in register [SRRAW](#) can be cleared by software by writing to the corresponding bit in register [SRCLR](#). All trap requests are combined to one common line and connected to a regular interrupt node of NVIC.

Note: When servicing an SCU service request, make sure that all related request flags are cleared after the identified request has been handled.

12.2.1.1 Service Request Sources

The SCU supports service request sources listed in [Table 12-1](#) and reflected in the [SRRAW](#), [SRMSK](#), [SRCLR](#) and [SRSET](#) registers. The events that trigger these service

System Control Unit (SCU)

requests are described in the respective module chapters or in the various sections within SCU.

Table 12-1 Service Requests

| Modules | Service Request Name | Service Request Short Name | SCU.SRx |
|---------|---------------------------------------|----------------------------|---------|
| NVM | Flash Double Bit ECC Event | FLECC2I | SR0 |
| | Flash Operation Complete Event | FLCMPLTI | |
| | 16kbytes SRAM Parity Error Event | PESRAMI | |
| | USIC0 SRAM Parity Error Event | PEU0I | |
| SCU:CCU | Loss of Clock Event | LOCI | SR1 |
| | Standby Clock Failure Event | SBYCLKFI | |
| SCU:PCU | VDDP Pre-warning Event | VDDPI | |
| | VDROP Event | VDROPI | |
| | VCLIP Event | VCLIPI | |
| SCU:GCU | Temperature Sensor Done Event | TSE_DONE | |
| | Temperature Sensor Compare High Event | TSE_HIGH | |
| | Temperature Sensor Compare Low Event | TSE_LOW | |
| WDT | WDT pre-warning | PRWARN | |
| RTC | RTC Periodic Event | PI | |
| | RTC Alarm | AI | |
| | RTC CTR Mirror Register Updated | RTC_CTR | |
| | RTC ATIM0 Mirror Register Updated | RTC_ATIM0 | |
| | RTC ATIM1 Mirror Register Updated | RTC_ATIM1 | |
| | RTC TIM0 Mirror Register Updated | RTC_TIM0 | |
| | RTC TIM1 Mirror Register Updated | RTC_TIM1 | |

12.2.2 SRAM Memory Content Protection

For supervising the content of the on-chip SRAM memories, the following mechanism is provided:

All on-chip SRAMs provide protection of content via parity checking. The parity logic generates additional parity bits which are stored along with each data word at a write operation. A read operation implies checking of the previous stored parity information.

System Control Unit (SCU)

An occurrence of a parity error is observable at the **SRRAW** status register. It is configurable via **SRMSK** whether a memory error should trigger an interrupt. It can also trigger a system reset when **RSTCON**.SPERSTEN or **RSTCON**.U0PERSTEN is set to 1. A parity control software test, such as to support in-system testing to fulfill Class B requirements, can be enabled with bit **PMTSR**.MTENS for the 16 kbytes SRAM memory individually. Once this bit is set, an inverted parity bit is generated during a write operation. When a read operation is performed on this SRAM address, a parity error shall be detected.

Note: Test software should be located in a different memory space.

12.2.3 Summary of ID

This section describes the various ID in XMC1100.

Module Identification

The module identification register indicates the function and the design step of each peripherals. Register **SCU_ID** is used for SCU module.

System ROM Table ID

The PID values in the system ROM table are defined in the **Table 12-2**. The XMC1100 system ROM table is located at F000 0000_H. Cortex-M0 ROM table is described in the debug chapter.

Table 12-2 PID Values of XMC1100 System ROM Table

| Name | Offset | Reference | Values |
|------|------------------|--|-----------------|
| PID0 | FE0 _H | XMC1100 Part Number [7:0] | ED _H |
| PID1 | FE4 _H | bits [7:4] JEP106 ID code [3:0] bits [3:0] XMC1100 Part Number [11:8] | 11 _H |
| PID2 | FE8 _H | bits [7:4] XMC1100 Revision bit [3] == 1: JEDEC assigned ID fields bits [2:0] JEP106 ID code [6:4] | 1C _H |
| PID3 | FEC _H | bits [7:4] RevAnd, minor revision field bits [3:0] if non-zero indicate a customer-modified block | 00 _H |
| PID4 | FD0 _H | bits [7:4] 4KB count bits [3:0] JEP106 continuation code | 00 _H |

Chip Identification Number

The chip identification number is a 8 word length number. It consists of the values in register DBGROMID, IDCHIP, register PAU_FLSIZE, register PAU_RAM0SIZE and register PAU_AVAILn(n=0-2) respectively. This number is for easy identification of product variants information of the device, example, package type, the temperature profile, flash size, RAM size and the peripheral availability.

12.3 Power Management (PCU)

Power management control is performed in the Power Control Unit (PCU).

12.3.1 Functional Description

The XMC1100 is running from a single external power supply of 1.8 - 5.5V (V_{DDP}). The main supply voltage is supervised by a supply watchdog.

The I/Os are running directly from the external supply voltage. The core voltage (V_{DDC}) is generated by an on-chip Embedded Voltage Regulator (EVR). The safe voltage range of the core voltage is supervised by a power validation circuit, which is part of the EVR.

12.3.2 System States

The system has the following general system states:

- Off
- Active
- Sleep
- Deep-Sleep

Figure 12-3 shows the state diagram and the transitions between the states.

Figure 12-3 System States Diagram

Active State

The active state is the normal operation state. The system is fully powered. The CPU is usually running from a high-speed clock. Depending on the application, the system clock might be slowed down. Unused peripherals might be stopped by gating the clock to these peripherals.

Sleep State

The sleep state of the system corresponds to the sleep state of the CPU. The state is entered via WFI or WFE instruction of the CPU. In this state, the clock to the CPU is stopped. To save power, the clock of the peripherals that are not needed during sleep state can be gated by register **CGATSET0** before entering sleep state.

The Flash can be put into shutdown mode during active state to achieve a further power reduction before entering sleep state via bit NVMCONF.NVM_ON. However, user code would have to be executed in SRAM before entering sleep state and after waking up from sleep state.

To avoid the switching of code execution to SRAM due to the shutdown of flash, register **PWRSVCR** can be used. When FPD bit is set, flash is shutdown only when the device has entered sleep state. The shut down operation is performed after the core has executed WFI/WFE instruction. After a wake-up event is detected, the system will resumed to the previous state i.e. the flash is operable again before the CPU can continue to fetch and execute the code. In this case, user code can be executed in Flash and no switching to SRAM is needed. In this approach, the wake-up time is longer because of the time needed for flash to reach the active state.

Peripherals can continue to operate unaffected and eventually generate an event to wake-up the CPU. In User with Debug mode (UMD) or User with Debug mode and HAR (UMHAR), a Debug HALT request is also able to wake-up the CPU. Any accordingly configured interrupt will bring the CPU back to operation via the NVIC or the M0 debug system.

Deep-Sleep State

The deep-sleep state is entered on the same mechanism as the sleep state with the addition that user code has enabled the deep-sleep state in system control register. This state is similar to sleep state, except that in deep-sleep state, the PCLK and MCLK will be switched to a slow standby clock and DCO1 will be put into power-down mode.

The shutting down of flash via NVMCONF.NVM_ON or PWRSVCR.FPD as explained in above section is applicable for deep-sleep mode.

Peripherals that continue to operate will run using the slow standby clock and can eventually generate an event to wake-up the CPU. In User with Debug mode (UMD) or User with Debug mode and HAR (UMHAR), a Debug HALT request is also able to wake-up the CPU. Any accordingly configured interrupt will bring the CPU back to operation

System Control Unit (SCU)

via the NVIC or the M0 debug system. The clock system is restored to the previous configuration for active state upon wake-up. Peripherals that are active will run with restored clock configuration.

The SRAM content is preserved in the deep-sleep state.

Note: It is recommended to slow down the PCLK and MCLK before entering deep sleep mode to prevent a sudden load change that could cause a brownout reset.

12.3.3 Embedded Voltage Regulator (EVR)

The EVR generates the core voltage V_{DDC} out of the external supplied voltage V_{DDP} . The EVR provides 2 supply monitoring detectors for the input voltage V_{DDP} . The generated core voltage V_{DDC} is monitored by a power validation circuit (PV).

12.3.4 Power-on Reset

The EVR starts operation as soon as V_{DDP} is above defined minimum level. It releases the reset, when the external voltage V_{DDP} and the generated voltage V_{DDC} are above the reset thresholds and reaching the nominal values.

12.3.5 Power Validation

A power validation circuit monitors the internal core supply voltage, V_{DDC} . It monitors that the core voltage is above the voltage threshold V_{DDCBO} which guarantees safe operation. Whenever the voltage falls below the threshold level, a brownout reset is generated.

12.3.6 Supply Voltage Monitoring

There are 2 detectors, namely, External voltage detector (VDEL) and External brownout detector (BDE) in the EVR that are used to monitor the V_{DDP} .

VDEL detector compares the supply voltage against a pre-warning threshold voltage. The threshold level is programmable via register ANAVDEL.VDEL_SELECT. An interrupt if enabled, will be triggered if a level below this threshold is detected and the flag, VDDPI, in SRRAW register bit is set. An indication bit, VDESR.VDDPPW, shows the output of the detector. During power-up, this indication bit can be polled to ensure that the external supply has reached the pre-warning voltage before starting the application code.

BDE detector is used to trigger a brownout reset when the V_{DDP} supply voltage drops below the defined threshold. Similarly, it is also used to ensure a proper startup during the power-up phase.

The Data Sheet defines the nominal value and applied hysteresis

12.3.7 V_{DDC} Response During Load Change

In XMC1100, the core voltage level, V_{DDC} , drops below the typical threshold when there is an increase in the load and rises when there is a decrease in the load. 2 detectors, VDROD and VCLIP detectors are used to monitor the lower limits and the upper limits of the core voltage level respectively (detectors details are described in the next section). A VDROD event happens when VDDC drops below the VDROD threshold voltage. A VCLIP event happens when VDDC rises above the VCLIP threshold voltage. Each of these events can trigger its dedicated interrupt if enabled via SRMSK register and the event status can be monitored via SRRAW register.

In XMC1100, the following scenarios may trigger a VDROD/VCLIP event due to load change:

- Changing the MCLK and PCLK frequency via CLKCR register
- Enabling/Gating the peripheral clock via the CGATSET0/CGATCLR0 registers

When a sudden load change happens ($< 4 \times \text{baseload}$ or $> 0.25 \times \text{baseload}$), regardless of an increase or decrease in load, the EVR needs time (15 μs) to regulate the core voltage back to a stable nominal voltage. During this period of time, the system is expected to maintain in the current load and no load change is allowed. Status bit VDDC2LOW and VDDC2HIGH in CRCLK register are used to indicate whether the voltage is stable.

Note: It is not recommended to increase the load more than 4 times of the baseload or decrease the load to less than 0.25 times of the baseload. If a bigger than the specified load change is required, the recommendation is to change the load in steps that each step is within the limits. For example, a final load of 16mA from the current baseload of 1mA needs at least 2 steps. A step from 1mA to 4mA followed by another step from 4mA to 16mA

The VDDC2LOW and VDDC2HIGH status bit is generated by a 10-bit counter using DCO1, 64MHz clock as the clock input. It is implemented to count the 16 μs (default) that is needed to have a stable V_{DDC} after a VDROD or VCLIP event happens. The length of this counter can be changed depending on the amount of load change via bit CLKCR.CNTADJ. The larger is the load change, the more is the time that user needs to wait for a stable clock. Refer to datasheet for a guideline of the current consumption of each module.

Using the example above, after programming some configuration that causes a change in load from 1mA to 4mA, user can poll for VDDC2LOW (CNTADJ=3FF_H) to ensure the 16 μs (max) needed to regulate EVR. After VDDC2LOW is set to 0, another load change from 4mA to 16mA can be performed and the cycle repeats for each step of load change.

During a VDROD event, clock blanking happens and the detail description is documented in **“Clock Blanking” on Page 12-17**. CPU clock and peripheral clocks continue to run during VCLIP event.

System Control Unit (SCU)

Note: When overflow event happens while the VDROP=1 (time to overflow based on the CNTADJ value is shorter than the time the device stays in a vdrop event), the 10-bit counter will automatically be restarted with the CNTADJ value.

Note: VDROP and VCLIP detectors are disabled during deep sleep mode.

12.3.8 Flash Power Control

The Flash module can be switched off to reduce static power. In sleep or deep-sleep state, it is dependent on the setting of register **PWRSVCR** whether the Flash module will be put to sleep or not in this state. The user has to evaluate the reduced leakage current against the longer startup time. In addition, the Flash can also be put to sleep using NVMCONF.NVM_ON before entering these power save modes.

12.4 Reset Control (RCU)

Reset Control Unit performs control of all reset related functionality including:

- Reset assertion on various reset request sources
- Inspection of reset sources after reset
- Selective reset of peripheral

12.4.1 Functional Description

The XMC1100 has the following reset types for the system:

- Master Reset, MRESET
- System Reset, SYSRESET

Master Reset, MRESET

Master reset is triggered by:

- Power-on reset (PORST)
- V_{DDP} or V_{DDC} undervoltage reset (also known as brownout reset)
- SW master reset via setting bit RSTCON.MRSTEN to 1

A complete reset to the device is executed by a master reset. Master reset is triggered by a power-on reset upon power-up. Whenever the supply V_{DDP} is ramped-up and crossing the V_{DDP} and V_{DDC} voltage threshold, the power-on reset is released. A power-on reset (also known as brown-out reset) is asserted again whenever the V_{DDP} voltage or the V_{DDC} voltage falls below reset thresholds. In additional, a master reset can be triggered by setting bit RSTCON.MRSTEN.

The sources that trigger a master reset also triggers a system reset SYSRESET.

System Reset, SYSRESET

System reset is triggered by:

- SW reset via Cortex M0 Application Interrupt and Reset Control Register (AIRCR)
- Lockup signal from Cortex M0 when enabled at RCU
- Watchdog reset
- Memory parity error when enabled
- Flash ECC double bit error when enabled
- Loss of clock when enabled
- sources that trigger a master reset

A system reset affects almost all logics. The only exceptions are RCU registers and Debug system when debug probe is present. The reset gets extended to the length defined by implementation requirements.

The debug system is reset by System Reset in normal operation mode when debug probe is not present. When debug probe is present, System Reset must not affect the Debug system.

12.4.2 Reset Status

The EVR provides the cause of a power on reset to the RCU. The reset cause can be inspected after resuming operation by reading register **RSTSTAT**. This register also indicates the source of event that causes the triggering of a system reset.

All registers of the RCU undergo reset only by a master reset except for RSTSTAT and RSTCON register. RSTSTAT register is only reset by a power-on reset and RSTCON is reset by any reset type.

*Note: Clearing of the reset status via register bit **RSTCLR.RSCLR** is strongly recommended to ensure a clear indication of the cause of next reset.*

Table 12-3 shows an overview of the reset signals their source and effects on the various parts of the system.

Table 12-3 Reset Overview

| Module/Function | Power-on Reset | Master Reset by SW bit | System Reset |
|-----------------|---------------------|------------------------|----------------------------------|
| CPU Core | yes | yes | yes |
| SCU | yes | yes | yes, except reset indication bit |
| Peripherals | yes | yes | yes |
| Debug System | yes | yes | see footnote ¹⁾²⁾ |
| Port Control | yes | yes | yes |
| SRAM | Affected,unreliable | Not affected | Not affected |
| Flash | yes | yes | yes |
| EVR | yes | no ³⁾ | no |
| Clock System | yes | yes | yes |

1) Debug system will be reset only if debug probe is not present.

2) Access to debug interface is disabled after every reset even when debug probe is present. See Warm Reset section of Debug System chapter for more details.

3) The supply to EVR will not be affected and hence a complete reset to EVR is not possible. However, it will be partially affected by the reset in the ANACTRL module.

12.5 Clock Control (CCU)

12.5.1 Features

The clock control unit CCU has the following functionality:

- Dedicated RTC and standby clock
- Clock Supervisory
 - Oscillator watchdog
- Wide range of frequency scaling of system frequencies
- Individual peripheral clock gating

12.5.2 Clock System and Control

Figure 12-4 shows the block diagram of the clock system in XMC1100. It consists of two oscillator (DCO1¹⁾ and DCO2) and a clock control unit (CCU). DCO1 has a clock output, dco1_dclk running at 64MHz. DCO2 is used to generate the standby clock running at 32.768kHz. The main clock, MCLK, and fast peripheral clock, PCLK, are generated from dco1_dclk. PCLK is running in either the same frequency as MCLK or double the frequency of MCLK. It is selectable via CLKCR.PCLKSEL.

Figure 12-4 shows the list of peripherals that are running in the PCLK domain. The rest of the peripherals except RTC and WDT are clocked by MCLK which is the same as the core and bus system. RTC and WDT is running at a frequency of 32.768kHz from the standby clock which is asynchronous to the MCLK and PCLK clock.

1) The accuracy of the DCO1 clock output can be improved by calibrating it based on the die temperature given by the temperature sensor. Refer to [Section 12.5.4](#) for detailed description

System Control Unit (SCU)

Figure 12-4 Clock System Block Diagram

Note: SHS(ADC) clock will not switched to standby clock source when there is a loss of clock event.

Fractional Divider

The frequency of MCLK and PCLK are programmable through a fractional divider. PCLK has a range of frequency from 125kHz to 64MHz and MCLK has a range from 125kHz to 32MHz.

The following formula calculate the MCLK clock frequency.

(12.1)

$$\left(\text{MCLK} = \frac{\text{dco_dclk}}{(2) \times \left(\text{IDIV} + \frac{\text{FDIV}}{256} \right)} \right) \text{ for IDIV} > 0$$

The following formula calculate the PCLK clock frequency when CLKCR.PCLKSEL is set to 1 and it is double the frequency of MCLK.

(12.2)

$$\left(\text{PCLK} = \frac{\text{dco_dclk}}{\left(\text{IDIV} + \frac{\text{FDIV}}{256} \right)} \right) \text{ for IDIV} > 0$$

IDIV represents an unsigned 8-bit integer from the bit field CLKCR.IDIV and FDIV/256 defines the fractional divider selection in CLKCR.FDIV. Changing of the MCLK and PCLK can be done within 2 clock cycles. While changing the frequency of MCLK clock and PCLK clock, it is recommended to disable all interrupts to prevent any access to flash that may results in an unsuccessful flash operation.

*Note: Changing the MCLK and PCLK frequency may result in a load change that causes clock blanking to happen. Refer to **Clock Blanking** and **VDDC Response During Load Change** for more details.*

Clock Blanking

To prevent a brown-out reset in case of a sudden positive load change, the clock blanking circuitry is used. It freezed the clock input to the fractional divider to regulate the

System Control Unit (SCU)

load change. The clock blanking only causes a small jitter if it is considered over a longer time period.

The clock blanking is activated when V_{DDC} is detected to be below the VDROPS threshold. Once the V_{DDC} is above this threshold, the enabled clocking is resume. This voltage drop detector is part of the EVR and it is activated by default upon any reset.

To monitor clock blanking activities, user can enable interrupt but can only enter ISR after the clock resume.

In addition to the use of clock blanking function to prevent a brown-out reset, the system is also expected to maintain in the current load and no further load change is allowed for 16 μ sec (max). Detail description of the core voltage behaviors during load change are described in **“VDDC Response During Load Change” on Page 12-11**.

As described in **“VDDC Response During Load Change” on Page 12-11**, the status bit CLKCR.VDDC2LOW is used to indicate to user that the core voltage, V_{DDC} , is below the nominal voltage and EVR is in the process of regulating it. During this period, the clock could be also not running in the selected speed and it is recommended to poll this bit before continuing with any large change to the current load.

Note: It is recommended to slow down the PCLK and MCLK before entering deep sleep mode to prevent a sudden load change that could cause a brownout reset when entering .

12.5.2.1 Oscillator Watchdog

The oscillator watchdog (OWD) monitors the DCO1 clock frequency using the standby clock as the reference clock. It can be disabled via OSCCSR.OWDEN. By setting bit OSCCSR.OWDRES¹⁾, the detection for DCO1 clock frequency can be restarted. The detection status output is only valid after some cycles of the standby clock frequency. When the OWD is disabled, the detection status will be reset and no detection is possible.

If the OWD is enabled before entering deep sleep mode, it will be disabled automatically by hardware when it enters deep sleep mode and re-enabled again after exiting deep sleep mode. The detection is reset and restarted after device wake-up from deep sleep mode.

12.5.2.2 Loss of Clock Detection and Recovery

Loss of clock happens when the oscillator watchdog (OWD) detects a DCO1 frequency that is less than 50 MHz or more than 68.5 MHz during normal operation. In this case,

1) It is recommended to clear the status bit SRRAW.LOCI and SRRAW.SBYCLKFI before restarting the detection.

System Control Unit (SCU)

an interrupt will be generated if it is enabled. Concurrently, the oscillator status flag, `OSCCSR.OSC2L` or `OSCCSR.OSC2H`, is set to 1 and the system clock will be provided by the standby clock of 32.768kHz. Emergency routines can be executed to safely shut down the system. Beside triggering an interrupt when the loss of clock happens, a system reset can also be triggered if it is enabled by `RSTCON.LOCRSTEN`.

Note: Switching to standby clock during loss of clock event happens only if DCO2 is still running (>0MHz). Bit `SRRAW.SBYCLKFI` indicates the fail status of the standby clock.

The XMC1100 remains in this loss of clock state until the next reset or after a successful clock recovery has been performed. A clock recovery could be carried out by restarting the detection by setting bit `OSCCSR.OWDRES`. Upon detecting a stable oscillator frequency of more than 50 MHz and lower than 68.5MHz, `OSC2L` and `OSC2H` will be set to 0 and the MCLK will switched automatically to the DCO1 clock source.

12.5.2.3 Standby Clock Failure

The standby clock failure event happens when the OWD detects a failure in standby clock where the clock stops running (~0kHz). Bit `SRRAW.SBYCLKFI` is set to 1 and trigger an interrupt via `SCU_SR1` service request if the interrupt is enabled in register `SRMSK`.

12.5.2.4 Startup Control for System Clock

When the XMC1100 starts up after reset, system frequency is provided by the DCO1 oscillator. After reset, CPU runs in 8MHz, default frequency. User can change the clock frequency that is used to execute the SSW and the user application code by defining it in the flash memory location 1000 1010_H. This feature allows the flexibility of device performance e.g. speed vs power consumption optimisation during start-up. For details, please refer to the section "Clock system handling by SSW" in the "Boot and Startup" chapter.

12.5.3 Clock Gating Control

The clock to peripherals can be individually gated and parts of the system can be stopped by registers `CGATSET0`. After a master reset, only core, memories, SCU and PORT peripheral are not clock gated. The rest of the peripherals are default clock gated. User can select the clock of individual modules to be enabled by SSW after reset by defining it in the flash memory location 1000 1014_H. Refer to Boot and Startup chapter for more details.

Load change during module clock enabling or gating

Enabling or gating the clock to peripherals could result in a load change that could cause clock blanking to happen. In addition, a load change of more than 4 times the current

System Control Unit (SCU)

load would required the system to maintain in the current load and no further load change is allowed for 16 usec (max). See **VDDC Response During Load Change** for more details.

Module clock gating in Sleep and Deep-Sleep modes

It is recommended to gate the clock using registers **CGATSET0** for module that is not needed during sleep mode or deep-sleep mode. These modules must be disabled before entering sleep or deep-sleep mode. In addition, the PCLK and MCLK will be switched to a slow standby clock and DCO1 will be put into power-down mode in deep-sleep mode.

12.5.4 Calibrating DCO based on Temperature

In XMC1100, DCO1 clock frequency can be calibrated during runtime to achieve a better accuracy. Based on the measured temperature using the on-chip temperature sensor(TSE), an offset value can be obtained using the formulae as shown below:

(12.3)

$$\text{OFFSET}[\text{steps}] = b + \frac{(a - b)(c - d)}{(e - d)}$$

where :

OFFSET value is range from 0 to 8

c is the measured temperature [°C]

a is constant DCO_ADJLO_T2

b is constant DCO_ADJLO_T1

d is constant ANA_TSE_T1

e is constant ANA_TSE_T2

The 4 constants in the formulae are stored in flash configuration page shown in **Table 12-4**.

Table 12-4 DCO calibration data in Flash sector 0 (CS0)

| Address | Length | Function |
|------------------------|--------|------------|
| DCO calibration data: | | |
| 1000'0F30 _H | 1 B | ANA_TSE_T1 |
| 1000'0F31 _H | 1 B | ANA_TSE_T2 |

Table 12-4 DCO calibration data in Flash sector 0 (CS0)

| Address | Length | Function |
|------------------------|--------|--------------|
| 1000'0F32 _H | 1 B | DCO_ADJLO_T1 |
| 1000'0F33 _H | 1 B | DCO_ADJLO_T2 |

Input the offset value (rounded to the nearest integer) to register bit **ANAOFFSET**.ADJL_OFFSET to start the DCO1 calibration. The offset value must be within the range of 0 to 8. This bit field is bit protected. DCO1 will take about 5 usec(max) for clock to be adjusted to the new frequency.

An example code is provided in the Oscillator Handling Device Guide.

12.6 Service Request Generation

The SCU module provides 2 service request outputs SR[1:0]. SR0 is for system critical request, such as loss of clock event. SR1 is for the common SCU request such as WDT pre-warning request. The service request outputs SR[1:0] are connected to interrupt nodes in the Nested Vectored Interrupt Controller (NVIC).

Refer to **Section 12.2.1** for more details.

12.7 Debug Behavior

The SCU module does not get affected with the HALTED signal from SCU upon debug activities performed using external debug probe.

12.8 Power, Reset and Clock

The SCU module implements functions that involve various types of modules controlled directly or via dedicated interfaces that are instantiated in different power, clock and reset domains. These modules are functionally considered parts of the SCU and therefore SCU is also considered a multi domain circuit in this sense.

Power domains:

Power domains get separated with appropriate power separation cells.

- Core domain supplied with V_{DDC} voltage
- Pad domain supplied with V_{DDP} voltage

Clock domains:

All cross-domain interfaces implement signal synchronization.

- internal SCU clock is MCLK, always identical to the CPU clock
- RTC and register mirror interface clock is 32.786 kHz clock generated from DCO2 oscillator

Reset domains:

All resets get internally synchronized to respective clocks.

- System Reset (SYSRESET) resets most of the logics in SCU and can be triggered from various sources (please refer to **Reset Control (RCU)** section for more details)
- Master Reset (MRESET) contributes in generation of the System Reset and gets triggered upon power-up sequence of the Core domain

System Control Unit (SCU)

12.9 Registers

This section describes the registers of SCU which some of them resides in the ANACTRL module. Most of the registers are reset by SYSRESET reset signal but some of the registers can be reset only with power-on reset. SCU registers are accessible via the AHB-lite bus. ANACTRL registers are accessible via the APB bus. ANACTRL registers have name starting with "ANA".

Table 12-5 Base Addresses of sub-sections of SCU registers

| Short Name | Description | Offset Addr. ¹⁾ |
|-------------------|--|----------------------------|
| GCU Registers | Offset address of General Control Unit | 0000 _H |
| PCU Registers | Offset address of Power Control Unit | 0200 _H |
| CCU Registers | Offset address of Clock Control Unit | 0300 _H |
| RCU Registers | Offset address of Reset Control Unit | 0400 _H |
| RTC Registers | Offset address of Real Time Clock Module | 0A00 _H |
| ANACTRL Registers | Offset address of ANACTRL registers | 1000 _H |

1) The absolute register address is calculated as follows:

Module Base Address + Sub-Module Offset Address (shown in this column) + Register Offset Address

Following access to SCU/ANACTRL SFRs result in an AHB/APB error response:

- Read or write access to undefined address
- Write access to read-only registers
- Write access to startup protected registers

Table 12-6 Registers Address Space

| Module | Base Address | End Address | Note |

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | | | | | | | OSC 2H | OSC 2L |
| r | | | | | | | | | | | | | | rh | rh |

| Field | Bits | Type | Description |
|-------|------|------|---|
| OSC2L | 0 | rh | Oscillator Valid Low Status Bit This bit indicates if the frequency output of OSC is usable. This is checked by the Oscillator Watchdog. 0 _B The OSC frequency is usable 1 _B The OSC frequency is not usable. Frequency is too low. |
| OSC2H | 1 | rh | Oscillator Valid High Status Bit This bit indicates if the frequency output of OSC is usable. This is checked by the Oscillator Watchdog. 0 _B The OSC frequency is usable 1 _B The OSC frequency is not usable. Frequency is too high. |

System Control Unit (SCU)

| Field | Bits | Type | Description |
|---------------|--------------------|------|---|
| OWDRES | 16 | rwh | Oscillator Watchdog Reset Setting this bit will restart the oscillator detection. This bit will be automatically reset to 0 after OWD is reset which takes 2 standby clock cycles due to synchronisation. 0_B The Oscillator Watchdog is not cleared and remains active 1_B The Oscillator Watchdog is cleared and restarted. The OSC2L and OSC2H flag will be held in the last value until it is updated after 3 standby clock cycles. |
| OWDEN | 17 | rw | Oscillator Watchdog Enable 0_B The Oscillator Watchdog is disabled 1_B The Oscillator Watchdog is enabled <i>Note: OSC2H and OSC2L will be cleared to 0 when OWD is disabled.</i> |

13 Pseudo Random Number Generator (PRNG)

13.1 Overview

The pseudo random bit generator (PRNG) provides random data with fast generation times.

13.1.1 Features

The PRNG includes the following features:

- Fast random data generation times:
 - 17 to 18 clock cycles generation time for 16-bit random data
 - 9 to 10 clock cycles generation time for 8-bit random data
- Fulfills statistical tests according to NIST-800

13.2 Description of Operation Modes

13.2.1 Key Loading Mode

Before the PRNG can be used it has to be initialized by the user software.

The key (seed) k of the PRNG is a bit string $k = (k_{n-1}, k_{n-2}, \dots, k_2, k_1, k_0)$ of length n . A key length of 80 bits is recommended, although smaller or larger key lengths are possible. It is recommended to use chip individual seed values.

The initialization of the PRNG consists of two basic phases:

1. Key loading
2. Warm-up

Key loading is initialized by setting the bit **PRNG_CTRL.KLD** to "1". In the key loading mode, **PRNG_WORD** acts always as a 16 bit destination register. The p partial words W_i ($0 \leq i < p$) of the key $k = (W_{p-1}, \dots, W_1, W_0)$, with $W_i = (k_{15}, \dots, k_1, k_0)$, are sequentially written to **PRNG_WORD** in the order W_0, W_1, \dots, W_{p-1} . A useful seed size is 80 bits (i.e., 5 data words, $p=5$). Because the bits of the partial key word are sequentially loaded into the internal state of the PRNG, loading of a key word will take 16 clock cycles. The **PRNG_CHK.RDV** flag is set to "0" while loading is in progress. A flag value of "1" indicates that the next partial key word can be written to **PRNG_WORD**.

After the complete key has been loaded, the **PRNG_CTRL.KLD** flag must be set to "0" to prepare the following warm-up phase. This operation takes one clock cycle.

The warm-up phase provides a thorough diffusion of the key bits. For this purpose the user must read and discard 64 random bits from the register **PRNG_WORD**. The

Pseudo Random Number Generator (PRNG)

random data output block must be set to either $b = 8$ or 16 bits. This is achieved by setting the corresponding value of the **PRNG_CTRL.RDBS** field.

The flag **PRNG_CHK.RDV** set to "1" indicates that the next random data block of width b can be read from **PRNG_WORD**.

If, for any reason, **PRNG_CTRL.RDBS** is reset to the default value of 00_B , the PRNG must be initialized once more – i.e., a key must be loaded and a warm-up phase carried out.

13.2.2 Streaming Mode

The flag **PRNG_CHK.RDV** set to 1_B indicates that the next random data block can be read from **PRNG_WORD**. After a word has been read the flag **PRNG_CHK.RDV** is reset to 0_B by the hardware and generation of new random bits starts. The PRNG requires 17–18 clock cycles to generate a 16 random bits and 9–10 clock cycles to generate eight random bits. From a software point of view it is not necessary to poll the **PRNG_CHK.RDV** flag. Consecutive read accesses to **PRNG_WORD** will be delayed automatically by hardware as long as **PRNG_CHK.RDV** is "0".

The width of the output data block is changed by setting the value of **PRNG_CTRL.RDBS**. This should be done before entering streaming mode, otherwise if the change is made during streaming, the new setting will not come into effect until the next generation cycle is started. The hardware checks that the selected number of bits are available and the flag **PRNG_CHK.RDV** is set when this condition is true.

In order to avoid reading a duplicate random byte when switching from 8-bit to 16-bit operation mode the last byte generated in the 8-bit mode should first be discarded before switching to 16-bit mode.

Note: PRNG_WORD should be accessed as 16 bit register, the upper 16 bits (of a 32 bit access) are ignored on a write and zeroes on a read and therefore contains no random data.

13.2.3 Refreshing and Restarting a Random Bit Stream

The random bit sequence can be refreshed with a new key. In this case the entropy contained in the last internal state is not cleared, but instead the new key is mixed into the current PRNG state. This is referred to as refreshing.

Refreshing is a means of introducing additional entropy into the generation of the random bit sequence. Without refreshing, the entire entropy rests in the initial key (or seed) that was used for initializing the PRNG during first key loading. Thereafter, the generation of the random bit sequence is purely deterministic. The deterministic process is broken whenever refreshing is performed. Refreshing implies that it is not possible to reproduce the same random result using the same key for data generation.

Since the internal state of the PRNG cannot be read and set directly, a sequence cannot be restored from any given state. A random bit sequence based on a certain initial key

Pseudo Random Number Generator (PRNG)

can, however, be continued. To this means, a segment s of the output sequence is stored and this segment is used as a initial key later on. The segment $s = (s_{n-1}, s_{n-2}, \dots, s_2, s_1, s_0)$ of length n should be fresh – i.e., generated after the last bits used in the application. The length of s should be at least $n = 80$ bits. This way a pseudorandom bit sequence can be continued after a system reset without requiring new key material. This process is known as restarting.

Note: Integration in a multi-application/multitasking environment together with the requirement to obtain a reproducible pseudorandom bit sequence would necessitate a state saving and restoring feature. Hence the OS must be able to save the PRNG state before giving control to application 2 and restore the state before returning control to application 1. This is not possible with the PRNG module.

13.3 Service Request Generation

The PRNG does not generate any service request.

13.4 Debug Behavior

The PRNG does not support a suspend mode while the system is halted by the debugger. That means that the PRNG continues its operation during debug halt.

13.5 Power, Reset and Clock

The PRNG module is located in the core power domain. The module can be reset to its default state by a system reset.

The PRNG module is clocked by the main clock, MCLK, from SCU.

13.6 Initialization and System Dependencies

The PRNG is always available after reset.

Refer to [Section 13.2.1](#) for the initialization steps.

13.7 Registers

The interface of the PRNG comprises the registers PRNG_WORD, PRNG_CHK and PRNG_CTRL.

Table 13-1 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| PRNG | 4802 0000 _H | 4802 000F _H | |

Pseudo Random Number Generator (PRNG)

Table 13-2 Registers Overview

| Register Short Name | Register Long Name | Offset Address | Page Number |
|--------------------------|----------------------------|-----------------|---------------------------|
| Data Registers | | | |
| PRNG_WORD | PRNG word register | 00 _H | Page 13-4 |
| PRNG_CHK | PRNG status check register | 04 _H | Page 13-5 |
| Control Registers | | | |
| PRNG_CTRL | PRNG control register | 0C _H | Page 13-6 |

The register is addressed wordwise.

13.7.1 Data Registers

Pseudo RNG Word Register

PRNG_WORD

PRNG Word Register

(00_H)

Reset Value: 0000_H

| Field | Bits | Type | Description |
|--------------|------|------|---|
| RDATA | 15:0 | rw | Random Data Random bit block or key to load. In the streaming mode the range of valid random bits is defined by the settings given by PRNG_CTRL.RDSB and the value of the flag PRNG_CHK.RDV. In the key loading mode the seed value (key) is written via this register. In this case, the key is written in units of 16 bits. |

Pseudo Random Number Generator (PRNG)

Additional Information

Notes

1. Reading `PRNG_WORD` while the PRNG is running in key loading mode (configured by setting `PRNG_CTRL.KLD`) will return the last value written to the register, whereas write accesses to the register while the PRNG is running in streaming mode (`PRNG_CTRL.KLD = '0'`) will be ignored.
2. Write access to `SFR PRNG_WORD`:
It is strongly recommended to wait until the SFR bit `PRNG_CHK.RDV` indicates that the register `PRNG_WORD` is ready to receive (new) data (which will be used to seed the PRNG.)
3. Read access to `SFR PRNG_WORD`:
It is strongly recommended to check the SFR bit `PRNG_CHK.RDV` before reading `SFR PRNG_WORD`.

Pseudo RNG Status Check Register

PRNG_CHK

PRNG Status Check Register

(04_H)

Reset Value: 0000_H

| | | | | | | | r | | | | | | | | r |

| Field | Bits | Type | Description |
|-------|------|------|---|
| RDV | 0 | r | Random Data / Key Valid Flag 0 _B INV , New random data block is not yet ready to be read. In " Key Loading Mode " on Page 13-1) this flag is set to 0 _B while loading is in progress. 1 _B VAL , Random data block is valid. In key loading mode this value indicates that the next partial key word can be written to PRNG_WORD . |
| 0 | 15:1 | r | Reserved |

Additional Information

*Note: If a word or byte is read from **PRNG_WORD** although the data is not ready (**PRNG_CHK.RDV** = 0_B), the system stalls until the data becomes ready.*

Pseudo Random Number Generator (PRNG)

13.7.2 Control Registers

Pseudo RNG Control Register

PRNG_CTRL

PRNG Control Register

(0C_H)

Reset Value: 0000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|---|---|---|---|---|---|-----|------|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | | | | | | | | | | | KLD | RDBS | | 0 |
| | | | | | | | | | | | | rw | rw | | r |

| Field | Bits | Type | Description |
|-------|------|------|--|
| KLD | 3 | rw | Key Load Operation Mode 0 _B STRM, Streaming mode (default) 1 _B KLD, Key loading mode |
| RDBS | 2:1 | rw | Random Data Block Size Set random data block size for read access (16 bits always used for key loading) 00 _B RES, Reset state (no random data block size defined) ¹⁾ , value of PRNG_WORD is undefined. 01 _B BYTE, 8 bits in PRNG_WORD.RDATA[7:0] 10 _B WORD, 16 bits in PRNG_WORD.RDATA[15:0] 11 _B RFU, Reserved for future use, value of PRNG_WORD is undefined. |
| 0 | 0 | r | Reserved |
| 0 | 15:4 | r | Reserved |

1) Once the reset value for RDBS (00_B) is set, the PRNG must be fully initialized before the functionality can be used. Initialization requires key loading, followed by a warm-up phase.

Additional Information

Note: It is recommended not to change the PRNG_CTRL.KLD flag during key load. Otherwise the distribution of the bits of the PRNG will not be equal.

14 Universal Serial Interface Channel (USIC)

The **Universal Serial Interface Channel** module (USIC) is a flexible interface module covering several serial communication protocols. A USIC module contains two independent communication channels named USICx_CH0 and USICx_CH1, with x being the number of the USIC module (e.g. channel 0 of USIC module 0 is referenced as USIC0_CH0). The user can program during run-time which protocol will be handled by each communication channel and which pins are used.

14.1 Overview

This section gives an overview about the feature set of the USIC.

14.1.1 Features

Each USIC channel can be individually configured to match the application needs, e.g. the protocol can be selected or changed during run time without the need for a reset. The following protocols are supported:

- **UART** (ASC, asynchronous serial channel)
 - Module capability: receiver/transmitter with max. baud rate $f_{\text{PERIPH}} / 4$

Universal Serial Interface Channel (USIC)

- Wide baud rate range down to single-digit baud rates
- Number of data bits per data frame: 1 to 63
- MSB or LSB first
- **LIN** Support by hardware (Local Interconnect Network)
 - Data transfers based on ASC protocol
 - Baud rate detection possible by built-in capture event of baud rate generator
 - Checksum generation under software control for higher flexibility
- **SSC/SPI** (synchronous serial channel with or without slave select lines)
 - Standard, Dual and Quad SPI format supported
 - Module capability: maximum baud rate $f_{\text{PERIPH}} / 2$, limited by loop delay
 - Number of data bits per data frame 1 to 63, more with explicit stop condition
 - Parity bit generation supported
 - MSB or LSB first
- **IIC** (Inter-IC Bus)
 - Application baud rate 100 kbit/s to 400 kbit/s
 - 7-bit and 10-bit addressing supported
 - Full master and slave device capability
- **IIS** (infotainment audio bus)
 - Module capability: maximum baud rate $f_{\text{PERIPH}} / 2$

Note: The real baud rates that can be achieved in a real application depend on the operating frequency of the device, timing parameters as described in the Data Sheet, signal delays on the PCB and timings of the peer device.

In addition to the flexible choice of the communication protocol, the USIC structure has been designed to reduce the system load (CPU load) allowing efficient data handling. The following aspects have been considered:

- **Data buffer capability**

The standard buffer capability includes a double word buffer for receive data and a single word buffer for transmit data. This allows longer CPU reaction times (e.g. interrupt latency).

- **Additional FIFO buffer capability**

In addition to the standard buffer capability, the received data and the data to be transmitted can be buffered in a FIFO buffer structure. The size of the receive and the transmit FIFO buffer can be programmed independently. Depending on the application needs, a total buffer capability of 64 data words can be assigned to the receive and transmit FIFO buffers of a USIC module (the two channels of the USIC module share the 64 data word buffer).

In addition to the FIFO buffer, a bypass mechanism allows the introduction of high-priority data without flushing the FIFO buffer.

- **Transmit control information**

For each data word to be transmitted, a 5-bit transmit control information has been added to automatically control some transmission parameters, such as word length, frame length, or the slave select control for the SPI protocol. The transmit control

Universal Serial Interface Channel (USIC)

information is generated automatically by analyzing the address where the user software has written the data word to be transmitted ($32 \text{ input locations} = 2^5 = 5 \text{ bit transmit control information}$).

This feature allows individual handling of each data word, e.g. the transmit control information associated to the data words stored in a transmit FIFO can automatically modify the slave select outputs to select different communication targets (slave devices) without CPU load. Alternatively, it can be used to control the frame length.

- **Flexible frame length control**

The number of bits to be transferred within a data frame is independent of the data word length and can be handled in two different ways. The first option allows automatic generation of frames up to 63 bits with a known length. The second option supports longer frames (even unlimited length) or frames with a dynamically controlled length.

- **Interrupt capability**

The events of each USIC channel can be individually routed to one of 6 service request outputs SR[5:0] available for each USIC module, depending on the application needs. Furthermore, specific start and end of frame indications are supported in addition to protocol-specific events.

- **Flexible interface routing**

Each USIC channel offers the choice between several possible input and output pins connections for the communications signals. This allows a flexible assignment of USIC signals to pins that can be changed without resetting the device.

- **Input conditioning**

Each input signal is handled by a programmable input conditioning stage with programmable filtering and synchronization capability.

- **Baud rate generation**

Each USIC channel contains its own baud rate generator. The baud rate generation can be based either on the internal module clock or on an external frequency input. This structure allows data transfers with a frequency that can not be generated internally, e.g. to synchronize several communication partners.

- **Transfer trigger capability**

In master mode, data transfers can be triggered by events generated outside the USIC module, e.g. by an input pin or a timer unit (transmit data validation). This feature allows time base related data transmission.

- **Debugger support**

The USIC offers specific addresses to read out received data without interaction with the FIFO buffer mechanism. This feature allows debugger accesses without the risk of a corrupted receive data sequence.

To reach a desired baud rate, two criteria have to be respected, the module capability and the application environment. The module capability is defined with respect to the module's input clock frequency, being the base for the module operation. Although the module's capability being much higher (depending on the module clock and the number

Universal Serial Interface Channel (USIC)

of module clock cycles needed to represent a data bit), the reachable baud rate is generally limited by the application environment. In most cases, the application environment limits the maximum reachable baud rate due to driver delays, signal propagation times, or due to EMI reasons.

Note: Depending on the selected additional functions (such as digital filters, input synchronization stages, sample point adjustment, data structure, etc.), the maximum reachable baud rate can be limited. Please also take care about additional delays, such as (internal or external) propagation delays and driver delays (e.g. for collision detection in ASC mode, for IIC, etc.).

Universal Serial Interface Channel (USIC)

A block diagram of the USIC module/channel structure is shown in **Figure 14-1**.

Figure 14-1 USIC Module/Channel Structure

Universal Serial Interface Channel (USIC)**14.2 Operating the USIC**

This section describes how to operate the USIC communication channel.

14.2.1 USIC Structure Overview

This section introduces the USIC structure.

14.2.1.1 Channel Structure

The USIC module contains two independent communication channels, with a structure as shown in [Figure 14-1](#).

The data shift unit and the data buffering of each channel support full-duplex data transfers. The protocol-specific actions are handled by the protocol pre-processors (PPP). In order to simplify data handling, an additional FIFO data buffer is optionally available for each USIC module to store transmit and receive data for each channel.

Due to the independent channel control and baud rate generation, the communication protocol, baud rate and the data format can be independently programmed for each communication channel.

14.2.1.2 Input Stages

For each protocol, the number of input signals used depends on the selected protocol. Each input signal is handled by an input stage (called DX_n, where n=0-5) for signal conditioning, such as input selection, polarity control, or a digital input filter. They can be classified according to their meaning for the protocols, see [Table 14-2](#).

The inputs marked as “optional” are not needed for the standard function of a protocol and may be used for enhancements. The descriptions of protocol-specific items are given in the related protocol chapters. For the external frequency input, please refer to the baud rate generator section, and for the transmit data validation, to the data handling section.

Universal Serial Interface Channel (USIC)
Table 14-2 Input Signals for Different Protocols

| Selected Protocol | Shift Data Input(s) (handled by DX0, DX3, DX4 and DX5)¹⁾ | Shift Clock Input (handled by DX1) | Shift Control Input (handled by DX2) |
|---|--|--|--|
| ASC, LIN | RXD | optional: external frequency input or TXD collision detection | optional: transmit data validation |
| Standard SSC, SPI (Master) | DIN0 (MRST, MISO) | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| Standard SSC, SPI (Slave) | DIN0 (MTSR, MOSI) | SCLKIN | SELIN |
| Dual- SSC, SPI (Master) | DIN[1:0] (MRST[1:0], MISO[1:0]) | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| Dual- SSC, SPI (Slave) | DIN[1:0] (MTSR[1:0], MOSI[1:0]) | SCLKIN | SELIN |
| Quad- SSC, SPI (Master) | DIN[3:0] (MRST[3:0], MISO[3:0]) | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| Quad- SSC, SPI (Slave) | DIN[3:0] (MTSR[3:0], MOSI[3:0]) | SCLKIN | SELIN |
| IIC | SDA | SCL | optional: transmit data validation |
| IIS (Master) | DIN0 | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| IIS (Slave) | DIN0 | SCLKIN | WAIN |

1) ASC, IIC, IIS and standard SSC protocols use only DX0 as the shift data input.

Universal Serial Interface Channel (USIC)

Note: To allow a certain flexibility in assigning required USIC input functions to port pins of the device, each input stage can select the desired input location among several possibilities.

The available USIC signals and their port locations are listed in the interconnects section, see [Page 14-226](#).

14.2.1.3 Output Signals

For each protocol, up to 14 protocol-related output signals are available. The number of actually used outputs depends on the selected protocol. They can be classified according to their meaning for the protocols, see [Table 14-3](#).

The outputs marked as “optional” are not needed for the standard function of a protocol and may be used for enhancements. The descriptions of protocol-specific items are given in the related protocol chapters. The MCLKOUT output signal has a stable frequency relation to the shift clock output (the frequency of MCLKOUT can be higher than for SCLKOUT) for synchronization purposes of a slave device to a master device. If the baud rate generator is not needed for a specific protocol (e.g. in SSC slave mode), the SCLKOUT and MCLKOUT signals can be used as clock outputs with 50% duty cycle with a frequency that can be independent from the communication baud rate.

Table 14-3 Output Signals for Different Protocols

| Selected Protocol | Shift Data Output(s) DOUT[3:0]¹⁾ | Shift Clock Output SCLKOUT | Shift Control Outputs SELO[7:0] | Master Clock Output MCLKOUT |
|-----------------------------------|--|---------------------------------------|--|--|
| ASC, LIN | TXD | not used | not used | optional: master time base |
| Standard SSC, SPI (Master) | DOUT0 (MSTR, MOSI) | master shift clock | slave select, chip select | optional: master time base |
| Standard SSC, SPI (Slave) | DOUT0 (MRST, MISO) | optional: independent clock output | not used | optional: independent clock output |
| Dual-SSC, SPI (Master) | DOUT[1:0] (MSTR[1:0], MOSI[1:0]) | master shift clock | slave select, chip select | optional: master time base |
| Dual-SSC, SPI (Slave) | DOUT[1:0] (MRST[1:0], MISO[1:0]) | optional: independent clock output | not used | optional: independent clock output |

Universal Serial Interface Channel (USIC)

Table 14-3 Output Signals for Different Protocols (cont'd)

| Selected Protocol | Shift Data Output(s) DOUT[3:0] ¹⁾ | Shift Clock Output SCLKOUT | Shift Control Outputs SELO[7:0] | Master Clock Output MCLKOUT |
|-------------------------------|---|---------------------------------------|------------------------------------|---------------------------------------|
| Quad-SSC, SPI (Master) | DOUT[3:0] (MSTR[3:0], MOSI[3:0]) | master shift clock | slave select, chip select | optional: master time base |
| Quad-SSC, SPI (Slave) | DOUT[3:0] (MRST[3:0], MISO[3:0]) | optional: independent clock output | not used | optional: independent clock output |
| IIC | SDA | SCL | not used | optional: master time base |
| IIS (master) | DOUT0 | master shift clock | WA | optional: master time base |
| IIS (slave) | DOUT0 | optional: independent clock output | not used | optional: independent clock output |

1) ASC, IIC, IIS and standard SSC protocols use only DOUT0 as the shift data output.

Note: To allow a certain flexibility in assigning required USIC output functions to port pins of the device, most output signals are made available on several port pins. The port control itself defines pin-by-pin which signal is used as output signal for a port pin (see port chapter). The available USIC signals and their port locations are listed in the interconnects section, see [Page 14-226](#).

14.2.1.4 Baud Rate Generator

Each USIC Channel contains a baud rate generator structured as shown in [Figure 14-2](#). It is based on coupled divider stages, providing the frequencies needed for the different protocols. It contains:

- A fractional divider to generate the input frequency $f_{\text{PIN}} = f_{\text{FD}}$ for baud rate generation based on the internal system frequency f_{PERIPH} .
- The DX1 input to generate the input frequency $f_{\text{PIN}} = f_{\text{DX1}}$ for baud rate generation based on an external signal.
- Two protocol-related counters: the divider mode counter to provide the master clock signal MCLK, the shift clock signal SCLK, and other protocol-related signals; and the capture mode timer for time interval measurement, e.g. baud rate detection.
- A time quanta counter associated to the protocol pre-processor defining protocol-specific timings, such shift control signals or bit timings, based on the input frequency f_{CTQIN} .

Universal Serial Interface Channel (USIC)

- The output signals MCLKOUT and SCLKOUT of the protocol-related divider that can be made available on pins. In order to adapt to different applications, some output characteristics of these signals can be configured.
 For device-specific details about availability of USIC signals on pins please refer to the interconnects section.

Figure 14-2 Baud Rate Generator

14.2.1.5 Channel Events and Interrupts

The notification of the user about events occurring during data traffic and data handling is based on:

- Data transfer events related to the transmission or reception of a data word, independent of the selected protocol.
- Protocol-specific events depending on the selected protocol.
- Data buffer events related to data handling by the optional FIFO data buffers.

14.2.1.6 Data Shifting and Handling

The data handling of the USIC module is based on an independent data shift unit (DSU) and a buffer structure that is similar for the supported protocols. The data shift and buffer registers are 16-bit wide (maximum data word length), but several data words can be concatenated to achieve longer data frames. The DSU inputs are the shift data (handled by input stage DX0, DX3, DX4 and DX5), the shift clock (handled by the input stage DX1), and the shift control (handled by the input stage DX2). The signal DOUT[3:0] represents the shift data outputs.

Universal Serial Interface Channel (USIC)

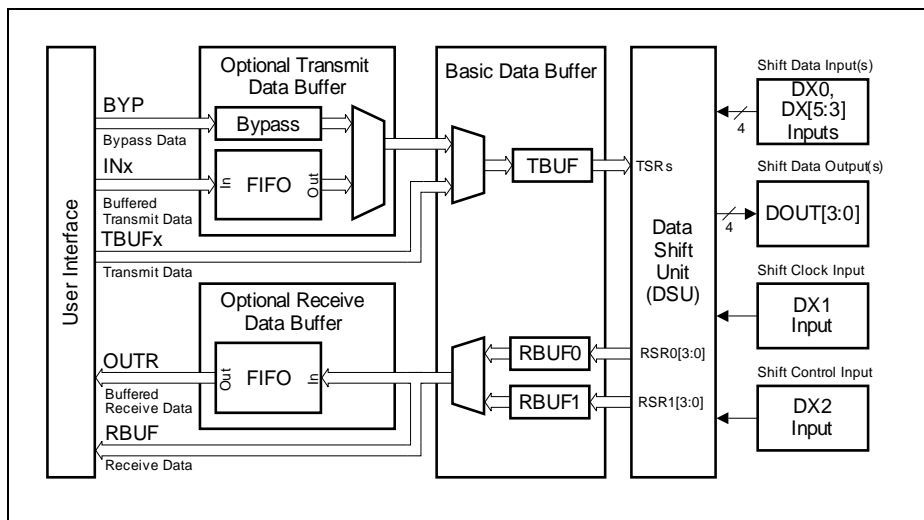

Figure 14-3 Principle of Data Buffering

The principle of data handling comprises:

- A transmitter with transmit shift registers (TSR and TSR[3:0]) in the DSU and a transmit data buffer (TBUF). A data validation scheme allows triggering and gating of data transfers by external events under certain conditions.
- A receiver with two alternating sets of receive shift registers (RSR0[3:0] and RSR1[3:0]) in the DSU and a double receive buffer structure (RBUF0, RBUF1). The alternating receive shift registers support the reception of data streams and data frames longer than one data word.
- A user interface to handle data, interrupts, and status and control information.

Basic Data Buffer Structure

The read access to received data and the write access of data to be transmitted can be handled by a basic data buffer structure.

The received data stored in the receiver buffers RBUF0/RBUF1 can be read directly from these registers. In this case, the user has to take care about the reception sequence to read these registers in the correct order. To simplify the use of the receive buffer structure, register RBUF has been introduced. A read action from this register delivers the data word received first (oldest data) to respect the reception sequence. With a read access from at least the low byte of RBUF, the data is automatically declared to be no longer new and the next received data word becomes visible in RBUF and can be read out next.

Universal Serial Interface Channel (USIC)

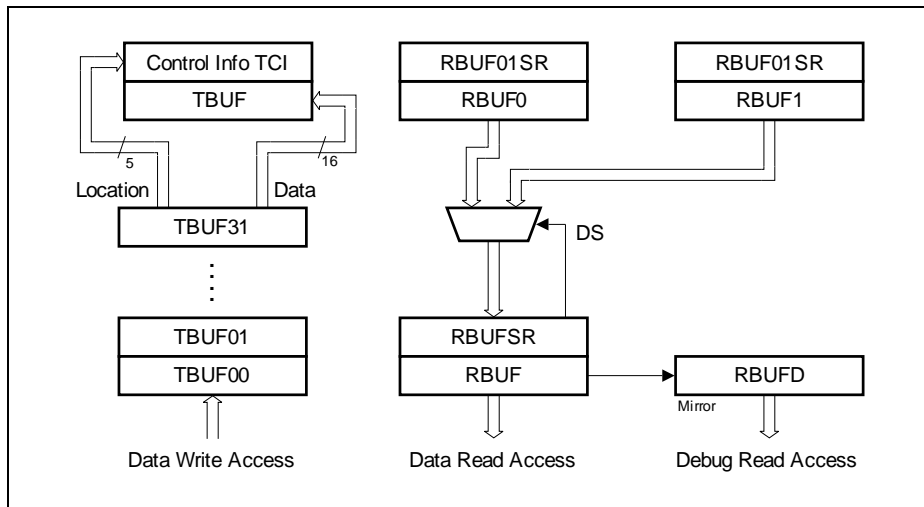

Figure 14-4 Data Access Structure without additional Data Buffer

It is recommended to read the received data words by accesses to RBUF and to avoid handling of RBUF0 and RBUF1. The USIC module also supports the use of debug accesses to receive data words. Debugger read accesses should not disturb the receive data sequence and, as a consequence, should not target RBUF. Therefore, register RBUFD has been introduced. It contains the same value as RBUF, but a read access from RBUFD does not change the status of the data (same data can be read several times). In addition to the received data, some additional status information about each received data word is available in the receiver buffer status register RBUF01SR (related to data in RBUF0 and RBUF1) and RBUFSR (related to data in RBUF).

Transmit data can be loaded to TBUF by software by writing to the transmit buffer input locations TBUF x ($x = 00-31$), consisting of 32 consecutive addresses. The data written to one of these input locations is stored in the transmit buffer TBUF. Additionally, the address of the written location is evaluated and can be used for additional control purposes. This 5-bit wide information (named **Transmit Control Information TCI**) can be used for different purposes in different protocols.

FIFO Buffer Structure

To allow easier data setup and handling, an additional data buffering mechanism can be optionally supported. The data buffer is based on the first-in-first-out principle (FIFO) that ensures that the sequence of transferred data words is respected.

If a FIFO buffer structure is used, the data handling scheme (data with associated control information) is similar to the one without FIFO. The additional FIFO buffer can be

Universal Serial Interface Channel (USIC)

independently enabled/disabled for transmission and reception (e.g. if data FIFO buffers are available for a specific USIC channel, it is possible to configure the transmit data path without and the receive data path with FIFO buffering).

The transmit FIFO buffer is addressed by using 32 consecutive address locations for INx instead of TBUFx (x=00-31) regardless of the FIFO depth. The 32 addresses are used to store the 5-bit TCI (together with the written data) associated with each FIFO entry.

The receive FIFO can be read out at two independent addresses, OUTR and OUTDR instead of RBUF and RBUFD. A read from the OUTR location triggers the next data packet to be available for the next read (general FIFO mechanism). In order to allow non-intrusive debugging (without risk of data loss), a second address location (OUTDR) has been introduced. A read at this location delivers the same value as OUTR, but without modifying the FIFO contents.

The transmit FIFO also has the capability to bypass the data stream and to load bypass data to TBUF. This can be used to generate high-priority messages or to send an emergency message if the transmit FIFO runs empty. The transmission control of the FIFO buffer can also use the transfer trigger and transfer gating scheme of the transmission logic for data validation (e.g. to trigger data transfers by events).

Note: The available size of a FIFO data buffer for a USIC channel depends on the specific device. Please refer to the implementation chapter for details about available FIFO buffer capability.

Universal Serial Interface Channel (USIC)

Figure 14-5 Data Access Structure with FIFO

14.2.2 Operating the USIC Communication Channel

This section describes how to operate a USIC communication channel, including protocol control and status, mode control and interrupt handling. The following aspects have to be taken into account:

- Enable the USIC module for operation and configure the behavior for the different device operation modes (see [Page 14-16](#)).
- Configure the pinning (refer to description in the corresponding protocol section).
- Configure the data structure (shift direction, word length, frame length, polarity, etc.).
- Configure the data buffer structure of the optional FIFO buffer area. A FIFO buffer can only be enabled if the related bit in register CCFG is set.
- Select a protocol by CCR.MODE. A protocol can only be selected if the related bit in register CCFG is set.

14.2.2.1 Protocol Control and Status

The protocol-related control and status information are located in the protocol control register PCR and in the protocol status register PSR. These registers are shared between the available protocols. As a consequence, the meaning of the bit positions in these registers is different within the protocols.

Use of PCR Bits

The signification of the bits in register PCR is indicated by the protocol-related alias names for the different protocols.

- PCR for the ASC protocol (see [Page 14-66](#))
- PCR for the SSC protocol (see [Page 14-98](#))
- PCR for the IIC protocol (see [Page 14-129](#))
- PCR for the IIS protocol (see [Page 14-147](#))

Use of PSR Flags

The signification of the flags in register PSR is indicated by the protocol-related alias names for the different protocols.

- PSR flags for the ASC protocol (see [Page 14-69](#))
- PSR flags for the SSC protocol (see [Page 14-102](#))
- PSR flags for the IIC protocol (see [Page 14-132](#))
- PSR flags for the IIS protocol (see [Page 14-150](#))

Universal Serial Interface Channel (USIC)

14.2.2.2 Mode Control

The mode control concept for system control tasks, such as suspend request for debugging, allows to program the module behavior under different device operating conditions. The behavior of a communication channel can be programmed for each of the device operating modes (normal operation, suspend mode). Therefore, each communication channel has an associated kernel state configuration register KSCFG defining its behavior in the following operating modes:

- **Normal operation:**
This operating mode is the default operating mode when no suspend request is pending. The module clock is not switched off and the USIC registers can be read or written. The channel behavior is defined by KSCFG.NOMCFG.
- **Suspend mode:**
This operating mode is requested when a suspend request is pending in the device. The module clock is not switched off and the USIC registers can be read or written. The channel behavior is defined by KSCFG.SUMCFG.

The four kernel modes defined by the register KSCFG are shown in [Table 14-4](#).

Table 14-4 USIC Communication Channel Behavior

| Kernel Mode | Channel Behavior | KSCFG. NOMCFG |
|-------------|---|------------------|
| Run mode 0 | Channel operation as specified, no impact on data transfer | 00 _B |
| Run mode 1 | | 01 _B |
| Stop mode 0 | Explicit stop condition as described in the protocol chapters | 10 _B |
| Stop mode 1 | | 11 _B |

Generally, bit field KSCFG.NOMCFG should be configured for run mode 0 as default setting for standard operation. If a communication channel should not react to a suspend request (and to continue its operation as in normal mode), bit field KSCFG.SUMCFG has to be configured with the same value as KSCFG.NOMCFG. If the communication channel should show a different behavior and stop operation when a specific stop condition is reached, the code for stop mode 0 or stop mode 1 have to be written to KSCFG.SUMCFG.

The stop conditions are defined for the selected protocol (see mode control description in the protocol section).

Note: The stop mode selection strongly depends on the application needs and it is very unlikely that different stop modes are required in parallel in the same application. As a result, only one stop mode type (either 0 or 1) should be used in the bit fields in register KSCFG. Do not mix stop mode 0 and stop mode 1 and avoid transitions

Universal Serial Interface Channel (USIC)

from stop mode 0 to stop mode 1 (or vice versa) for the same communication channel.

Note: In XMC1100, bit field KSCFG.SUMCFG is reset to its default value by any reset. If the suspend function is required during debugging, it is recommended that it is enabled in the user initialization code. Before programming the bit field, the module clock has to be enabled and special care needs to be taken while enabling the module clock as described in the CCU (Clock Gating Control) section of the SCU chapter.

14.2.2.3 General Channel Events and Interrupts

The general event and interrupt structure is shown in [Figure 14-6](#). If a defined condition is met, an event is detected and an event indication flag becomes automatically set. The flag stays set until it is cleared by software. If enabled, an interrupt can be generated if an event is detected. The actual status of the event indication flag has no influence on the interrupt generation. As a consequence, the event indication flag does not need to be cleared to generate further interrupts.

Additionally, the service request output SRx of the USIC channel that becomes activated in case of an event condition can be selected by an interrupt node pointer. This structure allows to assign events to interrupts, e.g. depending on the application, several events can share the same interrupt routine (several events activate the same SRx output) or can be handled individually (only one event activates one SRx output).

The SRx outputs are connected to interrupt control registers to handle the CPU reaction to the service requests. This assignment is described in the implementation section on [Page 14-153](#).

Figure 14-6 General Event and Interrupt Structure

14.2.2.4 Data Transfer Events and Interrupts

The data transfer events are based on the transmission or reception of a data word. The related indication flags are located in register PSR. All events can be individually enabled for interrupt generation.

- **Receive event to indicate that a data word has been received:**
If a new received word becomes available in the receive buffer RBUF0 or RBUF1, either a receive event or an alternative receive event occurs.
The receive event occurs if bit RBUFSR.PERR = 0. It is indicated by flag PSR.RIF and, if enabled, leads to receive interrupt.
- **Receiver start event to indicate that a data word reception has started:**
When the receive clock edge that shifts in the first bit of a new data word is detected and reception is enabled, a receiver start event occurs. It is indicated by flag PSR.RSIF and, if enabled, leads to transmit buffer interrupt.
In full duplex mode, this event follows half a shift clock cycle after the transmit buffer event and indicates when the shift control settings are internally “frozen” for the current data word reception and a new setting can be programmed.
In SSC and IIS mode, the transmit data valid flag TCSR.TDV is cleared in single shot mode with the receiver start event.
- **Alternative receive event to indicate that a specific data word has been received:**
If a new received word becomes available in the receive buffer RBUF0 or RBUF1, either a receive event or an alternative receive event occurs.
The alternative receive event occurs if bit RBUFSR.PERR = 1. It is indicated by flag PSR.AIF and, if enabled, leads to alternative receive interrupt.
Depending on the selected protocol, bit RBUFSR.PERR is set to indicate a parity error in ASC mode, the reception of the first byte of a new frame in IIC mode, and the WA information about right/left channel in IIS mode. In SSC mode, it is used as indication if the received word is the first data word, and is set if first and reset if not.
- **Transmit shift event to indicate that a data word has been transmitted:**
A transmit shift event occurs with the last shift clock edge of a data word. It is indicated by flag PSR.TSIF and, if enabled, leads to transmit shift interrupt.
- **Transmit buffer event to indicate that a data word transmission has been started:**
When a data word from the transmit buffer TBUF has been loaded to the shift register and a new data word can be written to TBUF, a transmit buffer event occurs. This happens with the transmit clock edge that shifts out the first bit of a new data word and transmission is enabled. It is indicated by flag PSR.TBIF and, if enabled, leads to transmit buffer interrupt.
This event also indicates when the shift control settings (word length, shift direction, etc.) are internally “frozen” for the current data word transmission.
In ASC and IIC mode, the transmit data valid flag TCSR.TDV is cleared in single shot mode with the transmit buffer event.
- **Data lost event to indicate a loss of the oldest received data word:**
If the data word available in register RBUF (oldest data word from RBUF0 or RBUF1)

Universal Serial Interface Channel (USIC)

has not been read out before it becomes overwritten with new incoming data, this event occurs. It is indicated by flag PSR.DLIF and, if enabled, leads to a protocol interrupt.

Table 14-5 shows the registers, bits and bit fields indicating the data transfer events and controlling the interrupts of a USIC channel.

Table 14-5 Data Transfer Events and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|---------------------------|-----------------|-----------------------|----------------------|------------------------|
| Standard receive event | PSR.RIF | PSCR.CRIF | CCR.RIEN | INPR.RINP |
| Receive start event | PSR.RSIF | PSCR.CRSIF | CCR.RSIEN | INPR.TBINP |
| Alternative receive event | PSR.AIF | PSCR.CAIF | CCR.AIEN | INPR.AINP |
| Transmit shift event | PSR.TSIF | PSCR.CTSIF | CCR.TSIEN | INPR.TSINP |
| Transmit buffer event | PSR.TBIF | PSCR.CTBIF | CCR.TBIEN | INPR.TBINP |
| Data lost event | PSR.DLIF | PSCR.CDLIF | CCR.DLIEN | INPR.PINP |

Figure 14-7 shows the two transmit events and interrupts.

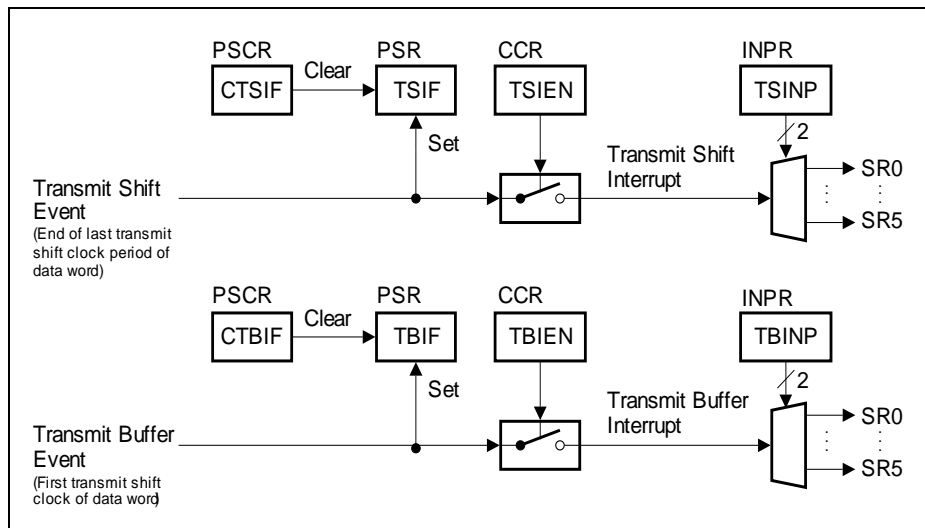

Figure 14-7 Transmit Events and Interrupts

Universal Serial Interface Channel (USIC)

Figure 14-8 shows the receive events and interrupts.

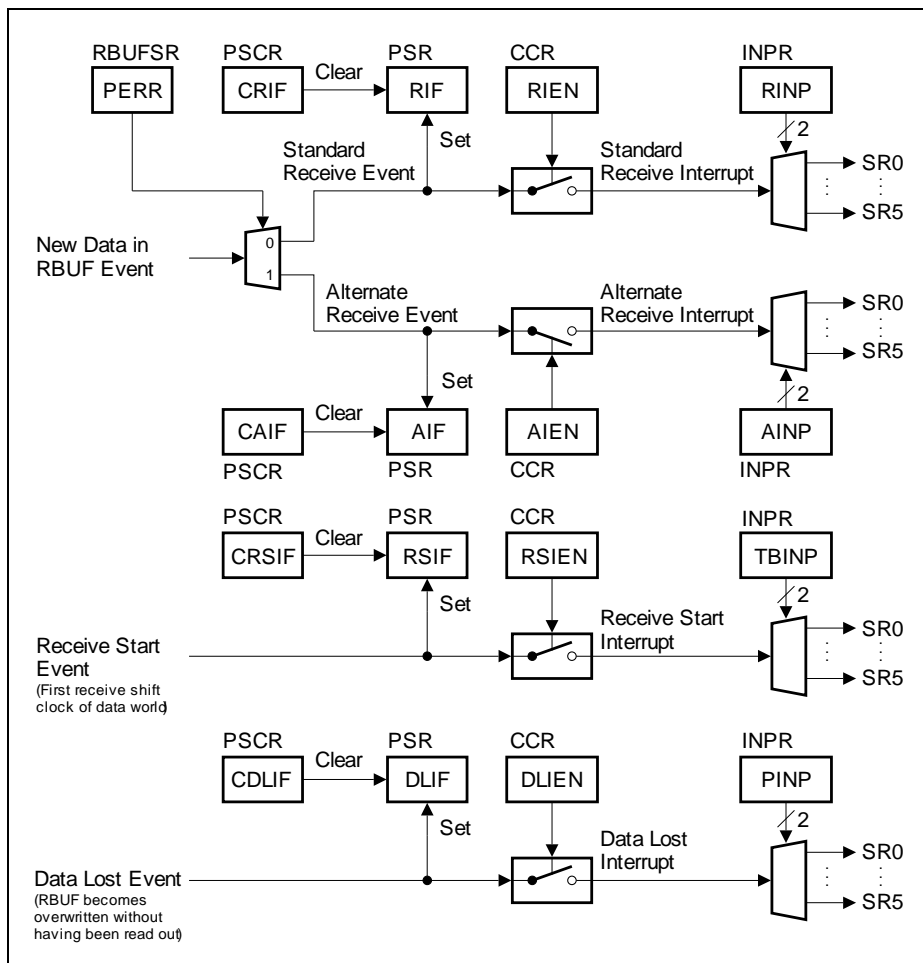

Figure 14-8 Receive Events and Interrupts

14.2.2.5 Baud Rate Generator Event and Interrupt

The baud rate generator event is based on the capture mode timer reaching its maximum value. It is indicated by flag **PSR.BRGIF** and, if enabled, leads to a protocol interrupt.

Universal Serial Interface Channel (USIC)

Table 14-6 shows the registers, bits and bit fields indicating the baud rate generator event and controlling the interrupt of a USIC channel.

Table 14-6 Baud Rate Generator Event and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|---------------------------|-----------------|-----------------------|----------------------|------------------------|
| Baud rate generator event | PSR. BRGIF | PSCR. CBRGIF | CCR. BRGIEN | INPR.PINP |

Figure 14-9 shows the baud rate generator event and interrupt.

Figure 14-9 Baud Rate Generator Event and Interrupt

Universal Serial Interface Channel (USIC)

14.2.2.6 Protocol-specific Events and Interrupts

These events are related to protocol-specific actions that are described in the corresponding protocol chapters. The related indication flags are located in register PSR. All events can be individually enabled for the generation of the common protocol interrupt.

- Protocol-specific events in ASC mode:
Synchronization break, data collision on the transmit line, receiver noise, format error in stop bits, receiver frame finished, transmitter frame finished
- Protocol-specific events in SSC mode:
MSLS event (start-end of frame in master mode), DX2T event (start/end of frame in slave mode), both based on slave select signals, parity error
- Protocol-specific events in IIC mode:
Wrong transmit code (error in frame sequence), start condition received, repeated start condition received, stop condition received, non-acknowledge received, arbitration lost, slave read request, other general errors
- Protocol-specific events in IIS mode:
DX2T event (change on WA line), WA falling edge or rising edge detected, WA generation finished

Table 14-7 Protocol-specific Events and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|--------------------------------------|-----------------|-----------------------|------------------------------|------------------------|
| Protocol-specific events in ASC mode | PSR.ST[8:2] | PSCR.CST[8:2] | PCR.CTR[7:3] | INPR.PINP |
| Protocol-specific events in SSC mode | PSR.ST[3:2] | PSCR.CST[3:2] | PCR.CTR[15:14] | INPR.PINP |
| Protocol-specific events in IIC mode | PSR.ST[8:1] | PSCR.CST[8:1] | PCR.CTR[24:18] | INPR.PINP |
| Protocol-specific events in IIS mode | PSR.ST[6:3] | PSCR.CST[6:3] | PCR.CTR[6:4], PCR.CTR[15] | INPR.PINP |

14.2.3 Operating the Input Stages

All input stages offer the same feature set. They are used for all protocols, because the signal conditioning can be adapted in a very flexible way and the digital filters can be switched on and off separately.

14.2.3.1 General Input Structure

There are generally two types of input stages, one for the data input stages DX0, DX[5:3] and the other for non-data input stages DX[2:1], as shown in [Figure 14-10](#) and [Figure 14-11](#). The difference is that for the data input stages, the input signal can be additionally selected from the port signal HWINn if hardware port control is enabled through CCR.HPCEN bit. All other enable/disable functions and selections are controlled independently for each input stage by bits in the registers DXnCR.

The desired input signal can be selected among the input lines DXnA to DXnG and a permanent 1-level by programming bit field DSEL (for the data input stages, hardware port control must be disabled for DSEL to take effect). Please refer to the interconnects section ([Section 14.12](#)) for the device-specific input signal assignment. Bit DPOL allows a polarity inversion of the selected input signal to adapt the input signal polarity to the internal polarity of the data shift unit and the protocol state machine. For some protocols, the input signals can be directly forwarded to the data shift unit for the data transfers (DSEN = 0, INSW = 1) without any further signal conditioning. In this case, the data path does not contain any delay due to synchronization or filtering.

In the case of noise on the input signals, there is the possibility to synchronize the input signal (signal DXnS is synchronized to f_{PERIPH}) and additionally to enable a digital noise filter in the signal path. The synchronized input signal (and optionally filtered if DFEN = 1) is taken into account by DSEN = 1. Please note that the synchronization leads to a delay in the signal path of 2-3 times the period of f_{PERIPH} .

Figure 14-10 Input Conditioning for DX0 and DX[5:3]

Universal Serial Interface Channel (USIC)

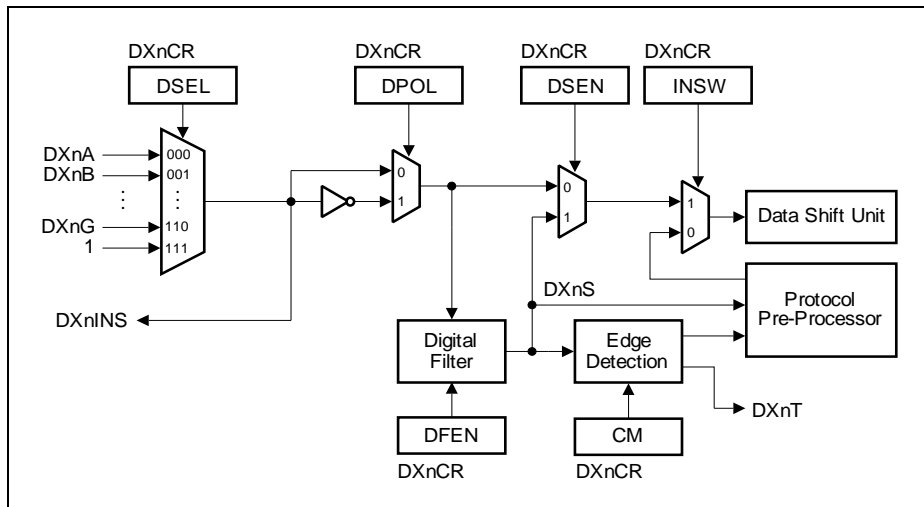

Figure 14-11 Input Conditioning for DX[2:1]

If the input signals are handled by a protocol pre-processor, the data shift unit is directly connected to the protocol pre-processor by $INSW = 0$. The protocol pre-processor is connected to the synchronized input signal $DXnS$ and, depending on the selected protocol, also evaluates the edges.

To support delay compensation in SSC and IIS protocols, the $DX1$ input stage additionally allows the receive shift clock to be controlled independently from the transmit shift clock through the bit $DCEN$. When $DCEN = 0$, the shift clock source is selected by $INSW$ and is the same for both receive and transmit. When $DCEN = 1$, the receive shift clock is derived from the selected input line as shown in [Figure 14-12](#).

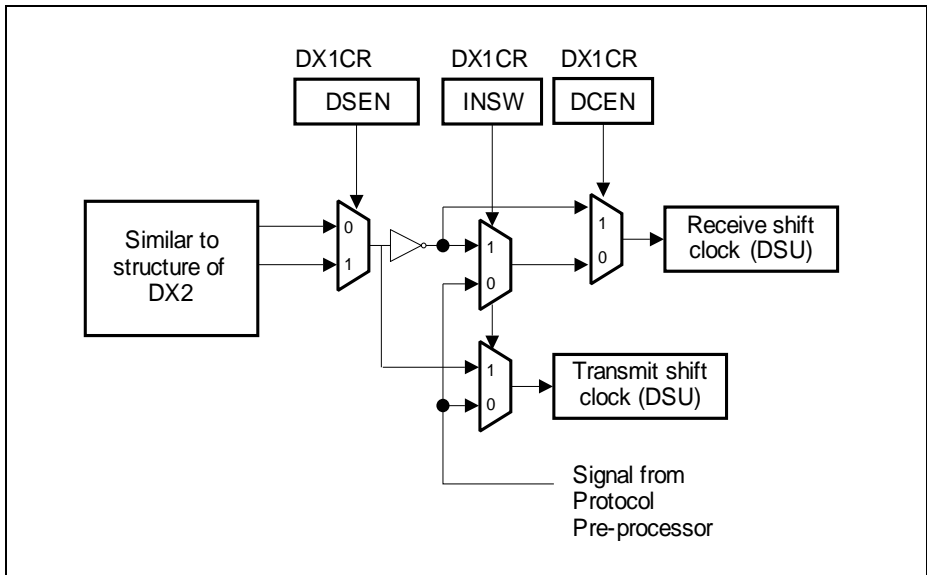

Figure 14-12 Delay Compensation Enable in DX1

14.2.3.2 Digital Filter

The digital filter can be enabled to reduce noise on the input signals. Before being filtered, the input signal becomes synchronized to f_{PERIPH} . If the filter is disabled, signal DXnS corresponds to the synchronized input signal. If the filter is enabled, pulses shorter than one filter sampling period are suppressed in signal DXnS. After an edge of the synchronized input signal, signal DXnS changes to the new value if two consecutive samples of the new value have been detected.

In order to adapt the filter sampling period to different applications, it can be programmed. The first possibility is the system frequency f_{PERIPH} . Longer pulses can be suppressed if the fractional divider output frequency f_{FD} is selected. This frequency is programmable in a wide range and can also be used to determine the baud rate of the data transfers.

In addition to the synchronization delay of 2-3 periods of f_{PERIPH} , an enabled filter adds a delay of up to two filter sampling periods between the selected input and signal DXnS.

14.2.3.3 Edge Detection

The synchronized (and optionally filtered) signal DXnS can be used as input to the data shift unit and is also an input to the selected protocol pre-processor. If the protocol pre-processor does not use the DXnS signal for protocol-specific handling, DXnS can be

Universal Serial Interface Channel (USIC)

used for other tasks, e.g. to control data transmissions in master mode (a data word can be tagged valid for transmission, see chapter about data buffering).

A programmable edge detection indicates that the desired event has occurred by activating the trigger signal DXnT (introducing a delay of one period of f_{PERIPH} before a reaction to this event can take place).

14.2.3.4 Selected Input Monitoring

The selected input signal of each input stage has been made available with the signals DXnINS. These signals can be used in the system to trigger other actions, e.g. to generate interrupts.

14.2.3.5 Loop Back Mode

The USIC transmitter output signals can be connected to the corresponding receiver inputs of the same communication channel in loop back mode. Therefore, the input "G" of the input stages that are needed for the selected protocol have to be selected. In this case, drivers for ASC, SSC, and IIS can be evaluated on-chip without the connections to port pins. Data transferred by the transmitter can be received by the receiver as if it would have been sent by another communication partner.

14.2.4 Operating the Baud Rate Generator

The following blocks can be configured to operate the baud rate generator, see also [Figure 14-2](#).

14.2.4.1 Fractional Divider

The fractional divider generates its output frequency f_{FD} by either dividing the input frequency f_{PERIPH} by an integer factor n or by multiplication of $n/1024$. It has two operating modes:

- Normal divider mode ($\text{FDR.DM} = 01_{\text{B}}$):
In this mode, the output frequency f_{FD} is derived from the input clock f_{PERIPH} by an integer division by a value between 1 and 1024. The division is based on a counter FDR.RESULT that is incremented by 1 with f_{PERIPH} . After reaching the value 3FF_{H} , the counter is loaded with FDR.STEP and then continues counting. In order to achieve $f_{\text{FD}} = f_{\text{PERIPH}}$, the value of STEP has to be programmed with 3FF_{H} .
The output frequency in normal divider mode is defined by the equation:

(14.1)

$$f_{\text{FD}} = f_{\text{PERIPH}} \times \frac{1}{n} \quad \text{with } n = 1024 - \text{STEP}$$

Universal Serial Interface Channel (USIC)

- Fractional divider mode ($FDR.DM = 10_B$):

In this mode, the output frequency f_{FD} is derived from the input clock f_{PERIPH} by a fractional multiplication of $n/1024$ for a value of n between 0 and 1023. In general, the fractional divider mode allows to program the average output clock frequency with a finer granularity than in normal divider mode. Please note that in fractional divider mode f_{FD} can have a maximum period jitter of one f_{PERIPH} period. This jitter is not accumulated over several cycles.

The frequency f_{FD} is generated by an addition of $FDR.STEP$ to $FDR.RESULT$ with f_{PERIPH} . The frequency f_{FD} is based on the overflow of the addition result over $3FF_H$. The output frequency in fractional divider mode is defined by the equation:

(14.2)

$$f_{FD} = f_{PERIPH} \times \frac{n}{1024} \quad \text{with } n = STEP$$

The output frequency f_{FD} of the fractional divider is selected for baud rate generation by $BRG.CLKSEL = 00_B$.

14.2.4.2 External Frequency Input

The baud rate can be generated referring to an external frequency input (instead of to f_{PERIPH}) if in the selected protocol the input stage DX1 is not needed ($DX1CTR.INSW = 0$). In this case, an external frequency input signal at the DX1 input stage can be synchronized and sampled with the system frequency f_{PERIPH} . It can be optionally filtered by the digital filter in the input stage. This feature allows data transfers with frequencies that can not be generated by the device itself, e.g. for specific audio frequencies.

If $BRG.CLKSEL = 10_B$, the trigger signal DX1T determines f_{DX1} . In this mode, either the rising edge, the falling edge, or both edges of the input signal can be used for baud rate generation, depending on the configuration of the DX1T trigger event by bit field $DX1CTR.CM$. The signal MCLK toggles with each trigger event of DX1T.

If $BRG.CLKSEL = 11_B$, the rising edges of the input signal can be used for baud rate generation. The signal MCLK represents the synchronized input signal DX1S.

Both, the high time and the low time of external input signal must each have a length of minimum 2 periods of f_{PERIPH} to be used for baud rate generation.

14.2.4.3 Divider Mode Counter

The divider mode counter is used for an integer division delivering the output frequency f_{PDIV} . Additionally, two divider stages with a fixed division by 2 provide the output signals MCLK and SCLK with 50% duty cycle. If the fractional divider mode is used, the maximum fractional jitter of 1 period of f_{PERIPH} can also appear in these signals. The output frequencies of this divider is controlled by register BRG.

Universal Serial Interface Channel (USIC)

In order to define a frequency ratio between the master clock MCLK and the shift clock SCLK, the divider stage for MCLK is located in front of the divider by PDIV+1, whereas the divider stage for SCLK is located at the output of this divider.

$$f_{\text{MCLK}} = \frac{f_{\text{PIN}}}{2} \quad (14.3)$$

$$f_{\text{SCLK}} = \frac{f_{\text{PDIV}}}{2} \quad (14.4)$$

In the case that the master clock is used as reference for external devices (e.g. for IIS components) and a fixed phase relation to SCLK and other timing signals is required, it is recommended to use the MCLK signal as input for the PDIV divider. If the MCLK signal is not used or a fixed phase relation is not necessary, the faster frequency f_{PIN} can be selected as input frequency.

$$\begin{aligned} f_{\text{PDIV}} &= f_{\text{PIN}} \times \frac{1}{\text{PDIV} + 1} & \text{if } \text{PPPEN} = 0 \\ f_{\text{PDIV}} &= f_{\text{MCLK}} \times \frac{1}{\text{PDIV} + 1} & \text{if } \text{PPPEN} = 1 \end{aligned} \quad (14.5)$$

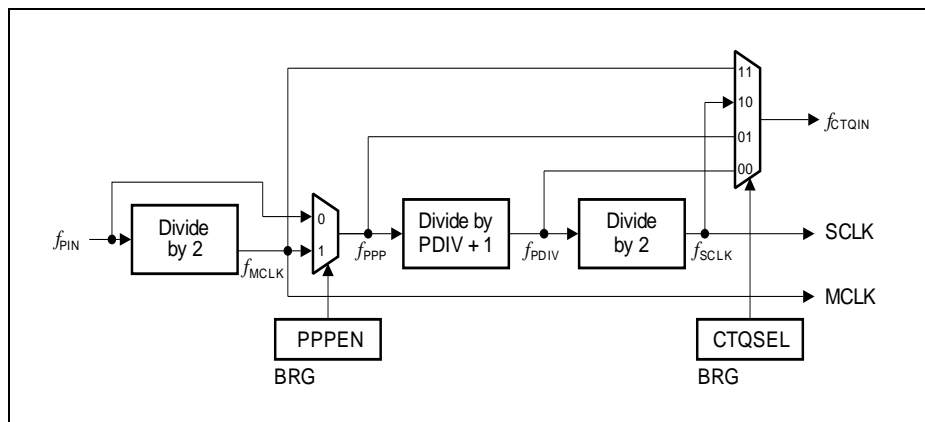

Figure 14-13 Divider Mode Counter

14.2.4.4 Capture Mode Timer

The capture mode timer is used for time interval measurement and is enabled by $\text{BRG.TMEN} = 1$. The timer works independently from the divider mode counter. Therefore, any serial data reception or transmission can continue while the timer is performing timing measurements. The timer counts f_{PPP} periods and stops counting

Universal Serial Interface Channel (USIC)

when it reaches its maximum value. Additionally, a baud rate generator interrupt event is generated (bit PSR.BRGIF becomes set).

If an event is indicated by DX0T or DX1T, the actual timer value is captured into bit field CMTR.CTV and the timer restarts from 0. Additionally, a transmit shift interrupt event is generated (bit PSR.TSIF becomes set).

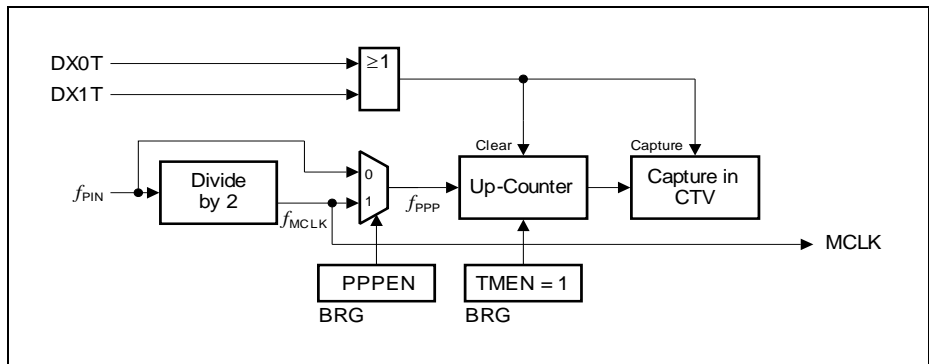

Figure 14-14 Protocol-Related Counter (Capture Mode)

The capture mode timer can be used to measure the baud rate in slave mode before starting or during data transfers, e.g. to measure the time between two edges of a data signal (by DX0T) or of a shift clock signal (by DX1T). The conditions to activate the DXnT trigger signals can be configured in each input stage.

14.2.4.5 Time Quanta Counter

The time quanta counter CTQ associated to the protocol pre-processor allows to generate time intervals for protocol-specific purposes. The length of a time quantum t_q is given by the selected input frequency f_{CTQIN} and the programmed pre-divider value.

The meaning of the time quanta depend on the selected protocol, please refer to the corresponding chapters for more protocol-specific information.

Figure 14-15 Time Quanta Counter

14.2.4.6 Master and Shift Clock Output Configuration

The master clock output signal MCLKOUT available at the corresponding output pin can be configured in polarity. The MCLK signal can be generated for each protocol in order to provide a kind of higher frequency time base compared to the shift clock.

The configuration mechanism of the master clock output signal MCLKOUT ensures that no shortened pulses can occur. Each MCLK period consists of two phases, an active phase, followed by a passive phase. The polarity of the MCLKOUT signal during the active phase is defined by the inverted level of bit BRG.MCLKCFG, evaluated at the start of the active phase. The polarity of the MCLKOUT signal during the passive phase is defined by bit BRG.MCLKCFG, evaluated at the start of the passive phase. If bit BRG.MCLKCFG is programmed with another value, the change is taken into account with the next change between the phases. This mechanism ensures that no shorter pulses than the length of a phase occur at the MCLKOUT output. In the example shown in [Figure 14-16](#), the value of BRG.MCLKCFG is changed from 0 to 1 during the passive phase of MCLK period 2.

The generation of the MCLKOUT signal is enabled/disabled by the protocol pre-processor, based on bit PCR.MCLK. After this bit has become set, signal MCLKOUT is generated with the next active phase of the MCLK period. If PCR.MCLK = 0 (MCLKOUT generation disabled), the level for the passive phase is also applied for active phase.

Figure 14-16 Master Clock Output Configuration

The shift clock output signal SCLKOUT available at the corresponding output pin can be configured in polarity and additionally, a delay of one period of f_{PDIV} (= half SCLK period) can be introduced. The delay allows to adapt the order of the shift clock edges to the application requirements. If the delay is used, it has to be taken into account for the calculation of the signal propagation times and loop delays.

The mechanism for the polarity control of the SCLKOUT signal is similar to the one for MCLKOUT, but based on bit field BRG.SCLKCFG. The generation of the SCLKOUT

Universal Serial Interface Channel (USIC)

signal is enabled/disabled by the protocol pre-processor. Depending on the selected protocol, the protocol pre-processor can control the generation of the SCLKOUT signal independently of the divider chain, e.g. for protocols without the need of a shift clock available at a pin, the SCLKOUT generation is disabled.

14.2.5 Operating the Transmit Data Path

The transmit data path is based on 16-bit wide transmit shift registers (TSR and TSR[3:0]) and a transmit buffer TBUF. The data transfer parameters like data word length, data frame length, or the shift direction are controlled commonly for transmission and reception by the shift control register SCTR. The transmit control and status register TCSR controls the transmit data handling and monitors the transmit status.

A change of the value of the data shift output signal DOUTx only happens at the corresponding edge of the shift clock input signal. The level of the last data bit of a data word/frame is held constant at DOUTx until the next data word begins with the next corresponding edge of the shift clock.

14.2.5.1 Transmit Buffering

The transmit shift registers can not be directly accessed by software, because they are automatically updated with the value stored in the transmit buffer TBUF if a currently transmitted data word is finished and new data is valid for transmission. Data words can be loaded directly into TBUF by writing to one of the transmit buffer input locations TBUFx (see [Page 14-33](#)) or, optionally, by a FIFO buffer stage (see [Page 14-39](#)).

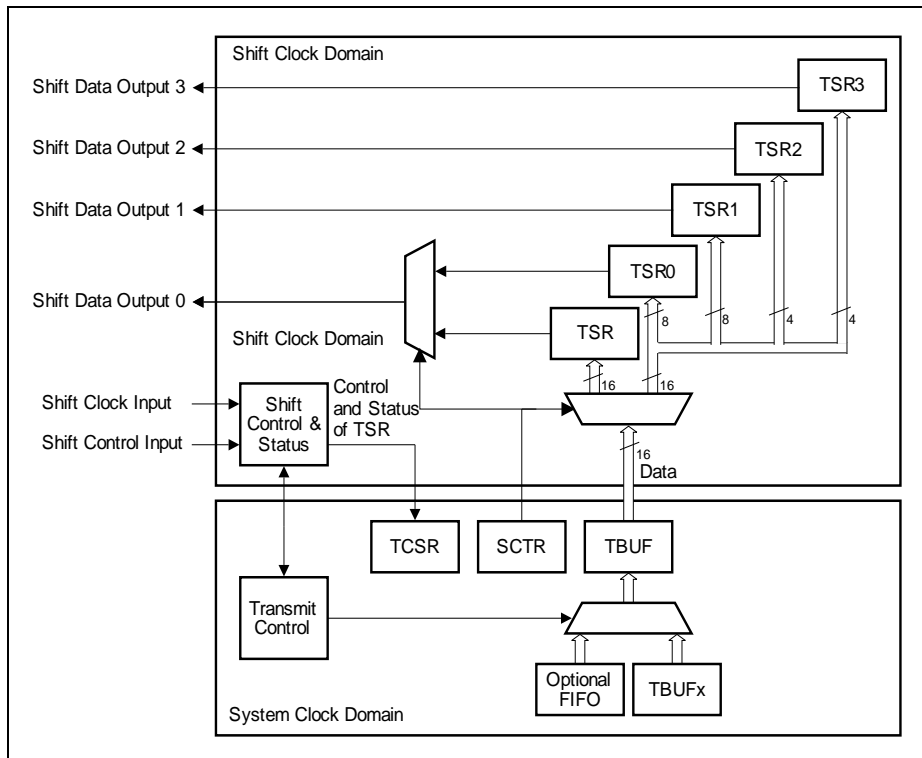

Figure 14-17 Transmit Data Path

14.2.5.2 Transmit Data Shift Mode

The transmit shift data can be selected to be shifted out one, two or four bits at a time through the corresponding number of output lines. This option allows the USIC to support protocols such as the Dual- and Quad-SSC. The selection is done through the bit field DSM in the shift control register SCTR.

Note: The bit field SCTR.DSM controls the data shift mode for both the transmit and receive paths to allow the transmission and reception of data through one to four data lines.

For the shift mode with two or four parallel data outputs, the data word and frame length must be in multiples of two or four respectively. The number of data shifts required to output a specific data word or data frame length is thus reduced by the factor of the number of parallel data output lines. For example, to transmit a 16-bit data word through four output lines, only four shifts are required.

Universal Serial Interface Channel (USIC)

Depending on the shift mode, different transmit shift registers with different bit composition are used as shown in [Table 14-8](#). Note that the 'n' in the table denotes the shift number less one, i.e. for the first data shift $n = 0$, the second data shift $n = 1$ and continues until the total number of shifts less one is reached.

For all transmit shift registers, whether the first bit shifted out is the MSB or LSB depends on the setting of SCTR.SDIR.

Table 14-8 Transmit Shift Register Composition

| Transmit Shift Registers | Single Data Output (SCTR.DSM = 00 _B) | Two Data Outputs (SCTR.DSM = 10 _B) | Four Data Outputs (SCTR.DSM = 11 _B) |
|--------------------------|--|--|---|
| TSR | All data bits | Not used | Not used |
| TSR0 | Not used | Bit $n*2$ | Bit $n*4$ |
| TSR1 | Not used | Bit $n*2 + 1$ | Bit $n*4 + 1$ |
| TSR2 | Not used | Not used | Bit $n*4 + 2$ |
| TSR3 | Not used | Not used | Bit $n*4 + 3$ |

14.2.5.3 Transmit Control Information

The transmit control information TCI is a 5-bit value derived from the address x of the written TBUF x or IN x input location. For example, writing to TBUF31 generates a TCI of 11111_B.

The TCI can be used as an additional control parameter for data transfers to dynamically change the data word length, the data frame length, or other protocol-specific functions (for more details about this topic, please refer to the corresponding protocol chapters). The way how the TCI is used in different applications can be programmed by the bits WLEMD, FLEMD, SELMD, WAMD and HPCMD in register TCSR. Please note that not all possible settings lead to useful system behavior.

- Word length control:
If TCSR.WLEMD = 1, bit field SCTR.WLE is updated with TCI[3:0] if a transmit buffer input location TBUF x is written. This function can be used in all protocols to dynamically change the data word length between 1 and 16 data bits per data word. Additionally, bit TCSR.EOF is updated with TCI[4]. This function can be used in SSC master mode to control the slave select generation to finish data frames. It is recommended to program TCSR.FLEMD = TCSR.SELMD = TCSR.WAMD = TCSR.HPCMD = 0.
- Frame length control:
If TCSR.FLEMD = 1, bit field SCTR.FLE[4:0] is updated with TCI[4:0] and SCTR.FLE[5] becomes 0 if a transmit buffer input location TBUF x is written. This function can be used in all protocols to dynamically change the data frame length

Universal Serial Interface Channel (USIC)

between 1 and 32 data bits per data frame. It is recommended to program $TCSR.SELMD = TCSR.WLEMD = TCSR.WAMD = TCSR.HPCMD = 0$.

- **Select output control:**
If $TCSR.SELMD = 1$, bit field $PCR.CTR[20:16]$ is updated with $TCI[4:0]$ and $PCR.CTR[23:21]$ becomes 0 if a transmit buffer input location $TBUFx$ is written. This function can be used in SSC master mode to define the targeted slave device(s). It is recommended to program $TCSR.WLEMD = TCSR.FLEMD = TCSR.WAMD = TCSR.HPCMD = 0$.
- **Word address control:**
If $TCSR.WAMD = 1$, bit $TCSR.WA$ is updated with $TCI[4]$ if a transmit buffer input location $TBUFx$ is written. This function can be used in IIS mode to define if the data word is transmitted on the right or the left channel. It is recommended to program $TCSR.WLEMD = TCSR.FLEMD = TCSR.SELMD = TCSR.HPCMD = 0$.
- **Hardware Port control:**
If $TCSR.HPCMD = 1$, bit field $SCTR.DSM$ is updated with $TCI[1:0]$ if a transmit buffer input location $TBUFx$ is written. This function can be used in SSC protocols to dynamically change the number of data input and output lines to set up for standard, dual and quad SSC formats.
Additionally, bit $TCSR.HPCDIR$ is updated with $TCI[2]$. This function can be used in SSC protocols to control the pin(s) direction when the hardware port control function is enabled through $CCR.HPCEN = 1$. It is recommended to program $TCSR.FLEMD = TCSR.WLEMD = TCSR.SELMD = TCSR.WAMD = 0$.

14.2.5.4 Transmit Data Validation

The data word in the transmit buffer $TBUF$ can be tagged valid or invalid for transmission by bit $TCSR.TDV$ (transmit data valid). A combination of data flow related and event related criteria define whether the data word is considered valid for transmission. A data validation logic checks the start conditions for each data word. Depending on the result of the check, the transmit shift register is loaded with different values, according to the following rules:

- If a USIC channel is the communication master (it defines the start of each data word transfer), a data word transfer can only be started with valid data in the transmit buffer $TBUF$. In this case, the transmit shift register is loaded with the content of $TBUF$, that is not changed due to this action.
- If a USIC channel is a communication slave (it can not define the start itself, but has to react), a data word transfer requested by the communication master has to be started independently of the status of the data word in $TBUF$. If a data word transfer is requested and started by the master, the transmit shift register is loaded at the first corresponding shift clock edge either with the data word in $TBUF$ (if it is valid for transmission) or with the level defined by bit $SCTR.PDL$ (if the content of $TBUF$ has not been valid at the transmission start). In both cases, the content of $TBUF$ is not changed.

Universal Serial Interface Channel (USIC)

The control and status bits for the data validation are located in register TCSR. The data validation is based on the logic blocks shown in **Figure 14-18**.

Figure 14-18 Transmit Data Validation

- A transfer gating logic enables or disables the data word transfer from TBUF under software or under hardware control. If the input stage DX2 is not needed for data shifting, signal DX2S can be used for gating purposes. The transfer gating logic is controlled by bit field TCSR.TDEN.
- A transfer trigger logic supports data word transfers related to events, e.g. timer based or related to an input pin. If the input stage DX2 is not needed for data shifting, signal DX2T can be used for trigger purposes. The transfer trigger logic is controlled by bit TCSR.TDVTR and the occurrence of a trigger event is indicated by bit TCSR.TE. For example, this can be used for triggering the data transfer upon receiving the Clear to Send (CTS) signal at DX2 in the RS-232 protocol.
- A data validation logic combining the inputs from the gating logic, the triggering logic and DSU signals. A transmission of the data word located in TBUF can only be started if the gating enables the start, bit TCSR.TDV = 1, and bit TCSR.TE = 1. The content of the transmit buffer TBUF should not be overwritten with new data while it is valid for transmission and a new transmission can start. If the content of TBUF has to be changed, it is recommended to clear bit TCSR.TDV by writing $\text{FMR.MTDV} = 10_{\text{B}}$ before updating the data. Bit TCSR.TDV becomes automatically set when TBUF is updated with new data. Another possibility are the interrupts TBI (for ASC and IIC) or RSI (for SSC and IIS) indicating that a transmission has started. While a transmission is in progress, TBUF can be loaded with new data. In this case the user has to take care that an update of the TBUF content takes place before a new transmission starts.

With this structure, the following data transfer functionality can be achieved:

Universal Serial Interface Channel (USIC)

- If bit TCSR.TDSSM = 0, the content of the transmit buffer TBUF is always considered as valid for transmission. The transfer trigger mechanism can be used to start the transfer of the same data word based on the selected event (e.g. on a timer base or an edge at a pin) to realize a kind of life-sign mechanism. Furthermore, in slave mode, it is ensured that always a correct data word is transmitted instead of the passive data level.
- Bit TCSR.TDSSM = 1 has to be programmed to allow word-by-word data transmission with a kind of single-shot mechanism. After each transmission start, a new data word has to be loaded into the transmit buffer TBUF, either by software write actions to one of the transmit buffer input locations TBUFx or by an optional data buffer (e.g. FIFO buffer). To avoid that data words are sent out several times or to allow data handling with an additional data buffer (e.g. FIFO), bit TCSR.TDSSM has to be 1.
- Bit TCSR.TDV becoming automatically set when a new data word is loaded into the transmit buffer TBUF, a transmission start can be requested by a write action of the data to be transmitted to at least the low byte of one of the transmit buffer input locations TBUFx. The additional information TCI can be used to control the data word length or other parameters independently for each data word by a single write access.
- Bit field FMR.MTDV allows software driven modification (set or clear) of bit TCSR.TDV. Together with the gating control bit field TCSR.TDEN, the user can set up the transmit data word without starting the transmission. A possible program sequence could be: clear TCSR.TDEN = 00_B, write data to TBUFx, clear TCSR.TDV by writing FMR.MTDV = 10_B, re-enable the gating with TCSR.TDEN = 01_B and then set TCSR.TDV under software control by writing FMR.MTDV = 01_B.

14.2.6 Operating the Receive Data Path

The receive data path is based on two sets of 16-bit wide receive shift registers RSR0[3:0] and RSR1[3:0] and a receive buffer for each of the set (RBUF0 and RBUF1). The data transfer parameters like data word length, data frame length, or the shift direction are controlled commonly for transmission and reception by the shift control registers.

Register RBUF01SR monitors the status of RBUF0 and RBUF1.

14.2.6.1 Receive Buffering

The receive shift registers cannot be directly accessed by software, but their contents are automatically loaded into the receive buffer registers RBUF0 (or RBUF1 respectively) if a complete data word has been received or the frame is finished. The received data words in RBUF0 or RBUF1 can be read out in the correct order directly from register RBUF or, optionally, from a FIFO buffer stage (see [Page 14-39](#)).

Universal Serial Interface Channel (USIC)

Figure 14-19 Receive Data Path

14.2.6.2 Receive Data Shift Mode

Receive data can be selected to be shifted in one, two or four bits at a time through the corresponding number of input stages and data input lines. This option allows the USIC to support protocols such as the Dual- and Quad-SSC. The selection is done through the bit field DSM in the shift control register SCTR.

Note: The bit field SCTR.DSM controls the data shift mode for both the transmit and receive paths to allow the transmission and reception of data through one to four data lines.

For the shift mode with two or four parallel data inputs, the data word and frame length must be in multiples of two or four respectively. The number of data shifts required to input a specific data word or data frame length is thus reduced by the factor of the

Universal Serial Interface Channel (USIC)

number of parallel data input lines. For example, to receive a 16-bit data word through four input lines, only four shifts are required.

Depending on the shift mode, different receive shift registers with different bit composition are used as shown in [Table 14-8](#). Note that the 'n' in the table denotes the shift number less one, i.e. for the first data shift $n = 0$, the second data shift $n = 1$ and continues until the total number of shifts less one is reached.

For all receive shift registers, whether the first bit shifted in is the MSB or LSB depends on the setting of SCTR.SDIR.

Table 14-9 Receive Shift Register Composition

| Receive Shift Registers | Input stage used | Single Data Input (SCTR.DSM = 00 _B) | Two Data Inputs (SCTR.DSM = 10 _B) | Four Data Inputs (SCTR.DSM = 11 _B) |
|-------------------------|------------------|---|---|--|
| RSRx0 | DX0 | All data bits | Bit $n*2$ | Bit $n*4$ |
| RSRx1 | DX3 | Not used | Bit $n*2 + 1$ | Bit $n*4 + 1$ |
| RSRx2 | DX4 | Not used | Not used | Bit $n*4 + 2$ |
| RSRx3 | DX5 | Not used | Not used | Bit $n*4 + 3$ |

14.2.6.3 Baud Rate Constraints

The following baud rate constraints have to be respected to ensure correct data reception and buffering. The user has to take care about these restrictions when selecting the baud rate and the data word length with respect to the module clock frequency f_{PERIPH} .

- A received data word in a receiver shift registers RSRx[3:0] must be held constant for at least 4 periods of f_{PERIPH} in order to ensure correct loading of the related receiver buffer register RBUFx.
- The shift control signal has to be constant inactive for at least 5 periods of f_{PERIPH} between two consecutive frames in order to correctly detect the end of a frame.
- The shift control signal has to be constant active for at least 1 period of f_{PERIPH} in order to correctly detect a frame (shortest frame).
- A minimum setup and hold time of the shift control signal with respect to the shift clock signal has to be ensured.

14.2.7 Hardware Port Control

Hardware port control is intended for SSC protocols with half-duplex configurations, where a single port pin is used for both input and output data functions, to control the pin direction through a dedicated hardware interface. All settings in Pn_IOCRy.PCx, except for the input pull device selection and output driver type (open drain or push-pull), are overruled by the hardware port control.

Universal Serial Interface Channel (USIC)

Input pull device selection is done through the Pn_IOCry.PC_x as before, while the output driver is fixed to push-pull-only in this mode.

One, two or four port pins can be selected with the hardware port control to support SSC protocols with multiple bi-directional data lines, such as dual- and quad-SSC. This selection and the enable/disable of the hardware port control is done through CCR.HPCEN. The direction of all selected pins is controlled through a single bit SCTR.HPCDIR.

SCTR.HPCDIR is automatically shadowed with the start of each data word to prevent changing of the pin direction in the middle of a data word transfer.

14.2.8 Operating the FIFO Data Buffer

The FIFO data buffers of a USIC module are built in a similar way, with transmit buffer and receive buffer capability for each channel. Depending on the device, the amount of available FIFO buffer area can vary. In the XMC1100, totally 64 buffer entries can be distributed among the transmit or receive FIFO buffers of both channels of the USIC module.

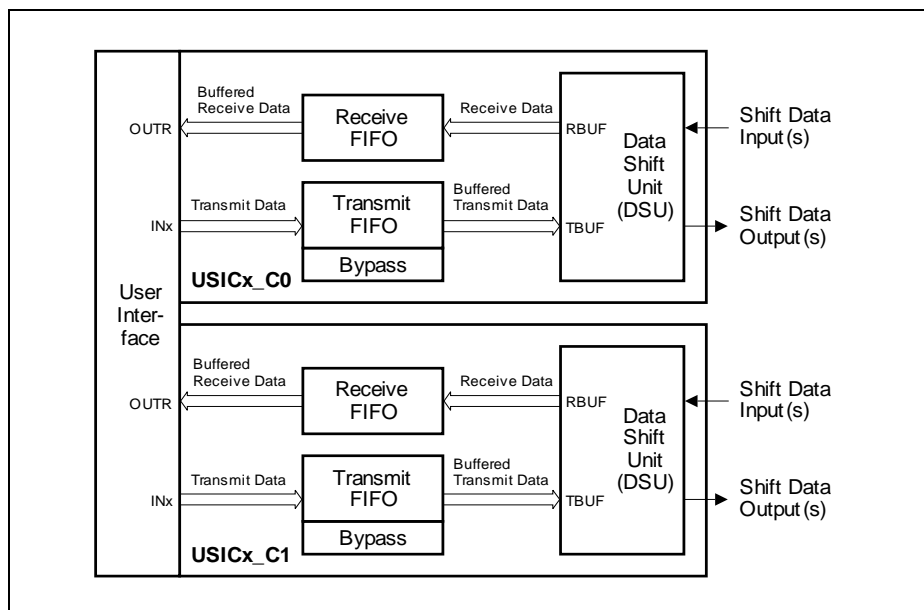

Figure 14-20 FIFO Buffer Overview

In order to operate the FIFO data buffers, the following issues have to be considered:

Universal Serial Interface Channel (USIC)

- FIFO buffer available and selected:
 The transmit FIFO buffer and the bypass structure are only available if CCFG.TB = 1, whereas the receive FIFO buffer is only available if CCFG.RB = 1.
 It is recommended to configure all buffer parameters while there is no data traffic for this USIC channel and the FIFO mechanism is disabled by TBCTR.SIZE = 0 (for transmit buffer) or RBCTR.SIZE = 0 (for receive buffer). The allocation of a buffer area by writing TBCTR or RBCTR has to be done while the corresponding FIFO buffer is disabled. The FIFO buffer interrupt control bits can be modified independently of data traffic.
- FIFO buffer setup:
 The total amount of available FIFO buffer entries limits the length of the transmit and receive buffers for each USIC channel.
- Bypass setup:
 In addition to the transmit FIFO buffer, a bypass can be configured as described on [Page 14-50](#).

14.2.8.1 FIFO Buffer Partitioning

If available, the FIFO buffer area consists of a defined number of FIFO buffer entries, each containing a data part and the associated control information (RCI for receive data, TCI for transmit data). One FIFO buffer entry represents the finest granularity that can be allocated to a receive FIFO buffer or a transmit FIFO buffer. All available FIFO buffer entries of a USIC module are located one after the other in the FIFO buffer area. The overall counting starts with FIFO entry 0, followed by 1, 2, etc.

For each USIC module, a certain number of FIFO entries is available, that can be allocated to the channels of the same USIC module. It is not possible to assign FIFO buffer area to USIC channels that are not located within the same USIC module.

For each USIC channel, the size of the transmit and the receive FIFO buffer can be chosen independently. For example, it is possible to allocate the full amount of available FIFO entries as transmit buffer for one USIC channel. Some possible scenarios of FIFO buffer partitioning are shown in [Figure 14-21](#).

Each FIFO buffer consists of a set of consecutive FIFO entries. The size of a FIFO data buffer can only be programmed as a power of 2, starting with 2 entries, then 4 entries, then 8 entries, etc. A FIFO data buffer can only start at a FIFO entry aligned to its size. For example, a FIFO buffer containing n entries can only start with FIFO entry 0, n , $2*n$, $3*n$, etc. and consists of the FIFO entries $[x*n, (x+1)*n-1]$, with x being an integer number (incl. 0). It is not possible to have "holes" with unused FIFO entries within a FIFO buffer, whereas there can be unused FIFO entries between two FIFO buffers.

Universal Serial Interface Channel (USIC)

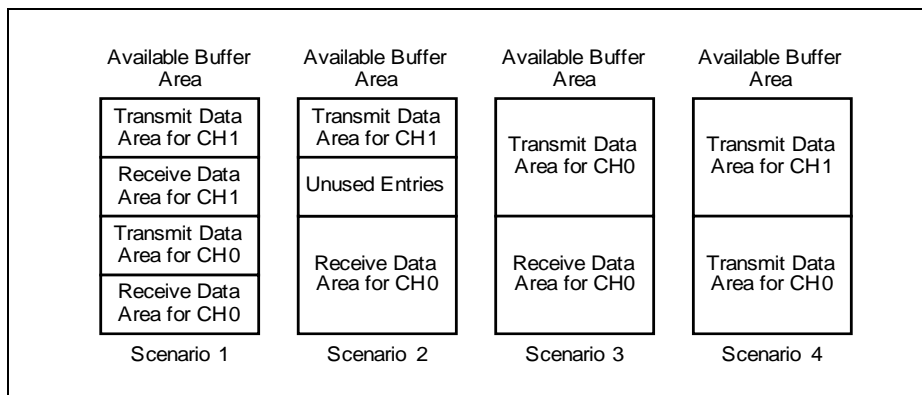

Figure 14-21 FIFO Buffer Partitioning

The data storage inside the FIFO buffers is based on pointers, that are internally updated whenever the data contents of the FIFO buffers have been modified. This happens automatically when new data is put into a FIFO buffer or the oldest data is taken from a FIFO buffer. As a consequence, the user program does not need to modify the pointers for data handling. Only during the initialization phase, the start entry of a FIFO buffer has to be defined by writing the number of the first FIFO buffer entry in the FIFO buffer to the corresponding bit field DPTR in register RBCTR (for a receive FIFO buffer) or TBCTR (for a transmit FIFO buffer) while the related bit field RBCTR.SIZE=0 (or TBCTR.SIZE = 0, respectively). The assignment of buffer entries to a FIFO buffer (regarding to size and pointers) must not be changed by software while the related USIC channel is taking part in data traffic.

14.2.8.2 Transmit Buffer Events and Interrupts

The transmit FIFO buffer mechanism detects the following events, that can lead to interrupts (if enabled):

- Standard transmit buffer event
- Transmit buffer error event

Standard Transmit Buffer Event

The standard transmit buffer event is triggered by the filling level of the transmit buffer (given by TRBSR.TBFLVL) exceeding (TBCTR.LOF = 1) or falling below (TBCTR.LOF = 0)¹⁾ a programmed limit (TBCTR.LIMIT).

¹⁾ If the standard transmit buffer event is used to indicate that new data has to be written to one of the INx locations, TBCTR.LOF = 0 should be programmed.

Universal Serial Interface Channel (USIC)

If the event trigger with TRBSR.STBT feature is disabled (TBCTR.STBTEN = 0), the trigger of the standard transmit buffer event is based on the transition of the fill level from equal to below or above the limit, not the fact of being below or above.

If TBCTR.STBTEN = 1, the transition of the fill level below or above the programmed limit additionally sets TRBSR.STBT. This bit triggers also the standard transmit buffer event whenever there is a transfer data to TBUF event or write data to INx event, depending on TBCTR.LOF setting.

The way TRBSR.STBT is cleared depends on the trigger mode (selected by TBCTR.STBTM). If TBCTR.STBTM = 0, TRBSR.STBT is cleared by hardware when the buffer fill level equals the programmed limit again (TRBSR.TBFLVL = TBCTR.LIMIT). If TBCTR.STBTM = 1, TRBSR.STBT is cleared by hardware when the buffer fill level equals the buffer size (TRBSR.TBFLVL = TBCTR.SIZE).

Note: The flag TRBSR.STBI is set only when the transmit buffer fill level exceeds or falls below the programmed limit (depending on TBCTR.LOF setting). Standard transmit buffer events triggered by TRBSR.STBT does not set the flag.

Figure 14-22 shows examples of the standard transmit buffer event with the different TBCTR.STBTEN and TBCTR.STBTM settings. These examples are meant to illustrate the hardware behaviour and might not always represent real application use cases.

Universal Serial Interface Channel (USIC)

Figure 14-22 Standard Transmit Buffer Event Examples

Transmit Buffer Error Event

The transmit buffer error event is triggered when software has written to a full buffer. The written value is ignored.

Universal Serial Interface Channel (USIC)

Transmit Buffer Events and Interrupt Handling

Figure 14-23 shows the transmit buffer events and interrupts.

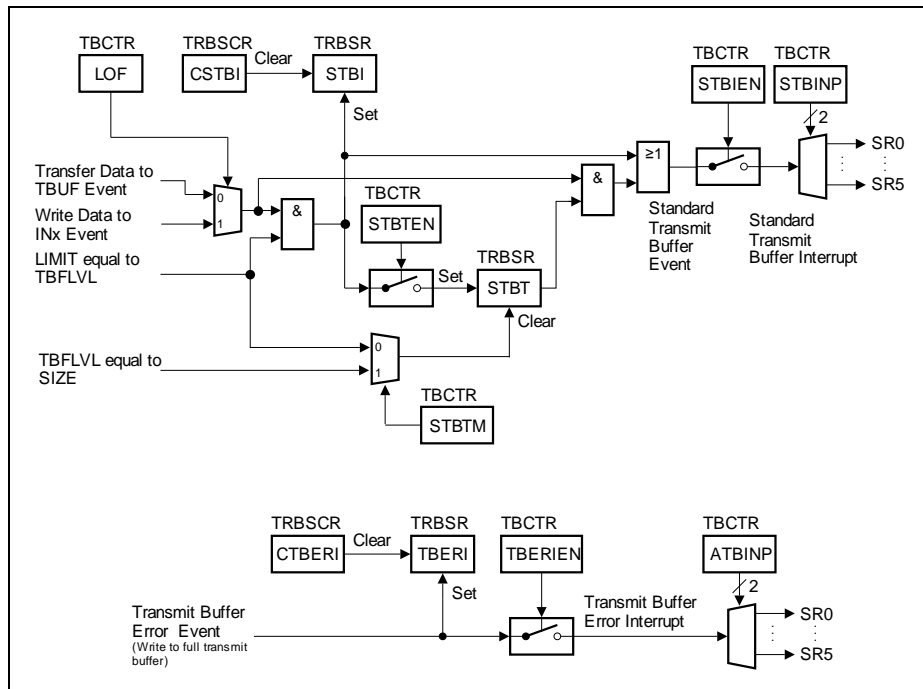

Figure 14-23 Transmit Buffer Events

Table 14-10 shows the registers, bits and bit fields to indicate the transmit buffer events and to control the interrupts related to the transmit FIFO buffers of a USIC channel.

Table 14-10 Transmit Buffer Events and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|--------------------------------|-----------------|-----------------------|----------------------|------------------------|
| Standard transmit buffer event | TRBSR. STBI | TRBSR. CSTBI | TBCTR. STBIEN | TBCTR. STBINP |
| | TRBSR. STBT | Cleared by hardware | | |
| Transmit buffer error event | TRBSR. TBERI | TRBSR. CTBERI | TBCTR. TBERIEN | TBCTR. ATBINP |

14.2.8.3 Receive Buffer Events and Interrupts

The receive FIFO buffer mechanism detects the following events, that can lead to an interrupt (if enabled):

- Standard receive buffer event
- Alternative receive buffer event
- Receive buffer error event

The standard receive buffer event and the alternative receive buffer event can be programmed to two different modes, one referring to the filling level of the receive buffer, the other one related to a bit position in the receive control information RCI of the data word that becomes available in OUTR.

If the interrupt generation refers to the filling level of the receive FIFO buffer, only the standard receive buffer event is used, whereas the alternative receive buffer event is not used. This mode can be selected to indicate that a certain amount of data has been received, without regarding the content of the associated RCI.

If the interrupt generation refers to RCI, the filling level is not taken into account. Each time a new data word becomes available in OUTR, an event is detected. If bit RCI[4] = 0, a standard receive buffer event is signaled, otherwise an alternative receive buffer device (RCI[4] = 1). Depending on the selected protocol and the setting of RBCTR.RCIM, the value of RCI[4] can hold different information that can be used for protocol-specific interrupt handling (see protocol sections for more details).

Standard Receive Buffer Event in Filling Level Mode

In filling level mode (RBCTR.RNM = 0), the standard receive buffer event is triggered by the filling level of the receive buffer (given by TRBSR.RBFLVL) exceeding (RBCTR.LOF = 1) or falling below (RBCTR.LOF = 0) a programmed limit (RBCTR.LIMIT).¹⁾

If the event trigger with bit TRBSR.SRBT feature is disabled (RBCTR.SRBTEN = 0), the trigger of the standard receive buffer event is based on the transition of the fill level from equal to below or above the limit, not the fact of being below or above.

If RBCTR.SRBTEN = 1, the transition of the fill level below or above the programmed limit additionally sets the bit TRBSR.SRBT. This bit also triggers the standard receive buffer event each time there is a data read out event or new data received event, depending on RBCTR.LOF setting.

The way TRBSR.SRBT is cleared depends on the trigger mode (selected by RBCTR.SRBTM). If RBCTR.SRBTM = 0, TRBSR.SRBT is cleared by hardware when the buffer fill level equals the programmed limit again (TRBSR.RBFLVL =

¹⁾ If the standard receive buffer event is used to indicate that new data has to be read from OUTR, RBCTR.LOF = 1 should be programmed.

Universal Serial Interface Channel (USIC)

RBCTR.LIMIT). If RBCTR.SRBTM = 1, TRBSR.SRBT is cleared by hardware when the buffer fill level equals 0 (TRBSR.RBFLVL = 0).

Note: The flag TRBSR.SRBI is set only when the receive buffer fill level exceeds or falls below the programmed limit (depending on RBCTR.LOF setting). Standard receive buffer events triggered by TRBSR.SRBT does not set the flag.

Universal Serial Interface Channel (USIC)

Figure 14-24 shows examples of the standard receive buffer event with the different RBCTR.SRBTEN and RBCTR.SRBTM settings. These examples are meant to illustrate the hardware behaviour and might not always represent real application use cases.

Figure 14-24 Standard Receive Buffer Event Examples

Universal Serial Interface Channel (USIC)

Standard and Alternate Receive Buffer Events in RCI Mode

In RCI mode ($RBCTR.RNM = 1$), the standard receive buffer event is triggered when the OUTR stage is updated with a new data value with $RCI[4] = 0$.

If the OUTR stage is updated with a new data value with $RCI[4] = 1$, an alternate receive buffer event is triggered instead.

Receive Buffer Error Event

The receive buffer error event is triggered if the software reads from an empty buffer, regardless of $RBCTR.RNM$ value. The read data is invalid.

Receive Buffer Events and Interrupt Handling

Figure 14-25 shows the receiver buffer events and interrupts in filling level mode.

14.2.8.4 FIFO Buffer Bypass

The data bypass mechanism is part of the transmit FIFO control block. It allows to introduce a data word in the data stream without modifying the transmit FIFO buffer contents, e.g. to send a high-priority message. The bypass structure consists of a bypass data word of maximum 16 bits in register BYP and some associated control information in register BYPCR. For example, these bits define the word length of the bypass data word and configure a transfer trigger and gating mechanism similar to the one for the transmit buffer TBUF.

The bypass data word can be tagged valid or invalid for transmission by bit BYRCR.BDV (bypass data valid). A combination of data flow related and event related criteria define whether the bypass data word is considered valid for transmission. A data validation logic checks the start conditions for this data word. Depending on the result of the check, the transmit buffer register TBUF is loaded with different values, according to the following rules:

- Data from the transmit FIFO buffer or the bypass data can only be transferred to TBUF if TCSR.TDV = 0 (TBUF is empty).
- Bypass data can only be transferred to TBUF if the bypass is enabled by BYPCR.BDEN or the selecting gating condition is met.
- If the bypass data is valid for transmission and has either a higher transmit priority than the FIFO data or if the transmit FIFO is empty, the bypass data is transferred to TBUF.
- If the bypass data is valid for transmission and has a lower transmit priority than the FIFO buffer that contains valid data, the oldest transmit FIFO data is transferred to TBUF.
- If the bypass data is not valid for transmission and the FIFO buffer contains valid data, the oldest FIFO data is transferred to TBUF.
- If neither the bypass data is valid for transmission nor the transmit FIFO buffer contains valid data, TBUF is unchanged.

The bypass data validation is based on the logic blocks shown in [Figure 14-27](#).

- A transfer gating logic enables or disables the bypass data word transfer to TBUF under software or under hardware control. If the input stage DX2 is not needed for

Universal Serial Interface Channel (USIC)

data shifting, signal DX2S can be used for gating purposes. The transfer gating logic is controlled by bit BYPCR.BDEN.

- A transfer trigger logic supports data word transfers related to events, e.g. timer based or related to an input pin. If the input stage DX2 is not needed for data shifting, signal DX2T can be used for trigger purposes. The transfer trigger logic is controlled by bit BYPCR.BDVTR.
- A bypass data validation logic combining the inputs from the gating logic, the triggering logic and TCSR.TDV.

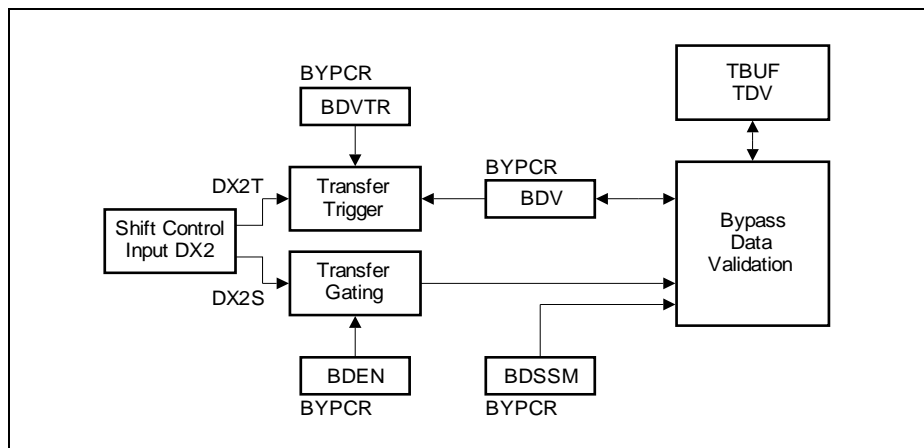

Figure 14-27 Bypass Data Validation

With this structure, the following bypass data transfer functionality can be achieved:

- Bit BYPCR.BDSSM = 1 has to be programmed for a single-shot mechanism. After each transfer of the bypass data word to TBUF, the bypass data word has to be tagged valid again. This can be achieved either by writing a new bypass data word to BYP or by DX2T if BDVTR = 1 (e.g. trigger on a timer base or an edge at a pin).
- Bit BYPCR.BDSSM = 0 has to be programmed if the bypass data is permanently valid for transmission (e.g. as alternative data if the data FIFO runs empty).

14.2.8.5 FIFO Access Constraints

The data in the shared FIFO buffer area is accessed by the hardware mechanisms for data transfer of each communication channel (for transmission and reception) and by software to read out received data or to write data to be transmitted. As a consequence, the data delivery rate can be limited by the FIFO mechanism. Each access by hardware to the FIFO buffer area has priority over a software access, that is delayed in case of an access collision.

In order to avoid data loss and stalling of the CPU due to delayed software accesses, the

Universal Serial Interface Channel (USIC)

baud rate, the word length and the software access mechanism have to be taken into account. Each access to the FIFO data buffer area by software or by hardware takes one period of f_{PERIPH} . Especially a continuous flow of very short, consecutive data words can lead to an access limitation.

14.2.8.6 Handling of FIFO Transmit Control Information

In addition to the transmit data, the transmit control information TCI can be transferred from the transmit FIFO or bypass structure to the USIC channel. Depending on the selected protocol and the enabled update mechanism, some settings of the USIC channel parameters can be modified. The modifications are based on the TCI of the FIFO data word loaded to TBUF or by the bypass control information if the bypass data is loaded into TBUF.

- TCSR.SELMD = 1: update of PCR.CTR[20:16] by FIFO TCI or BYPCR.BSELO with additional clear of PCR.CTR[23:21]
- TCSR.WLEMD = 1: update of SCTR.WLE and TCSR.EOF by FIFO TCI or BYPCR.BWLE (if the WLE information is overwritten by TCI or BWLE, the user has to take care that FLE is set accordingly)
- TCSR.FLEMD = 1: update of SCTR.FLE[4:0] by FIFO TCI or BYPCR.BWLE with additional clear of SCTR.FLE[5]
- TCSR.HPCMD = 1: update of SCTR.DSM and SCTR.HPCDIR by FIFO TCI or BYPCR.BHPC
- TCSR.WAMD = 1: update of TCSR.WA by FIFO TCI[4]

See [Section 14.2.5.3](#) for more details on TCI.

Universal Serial Interface Channel (USIC)

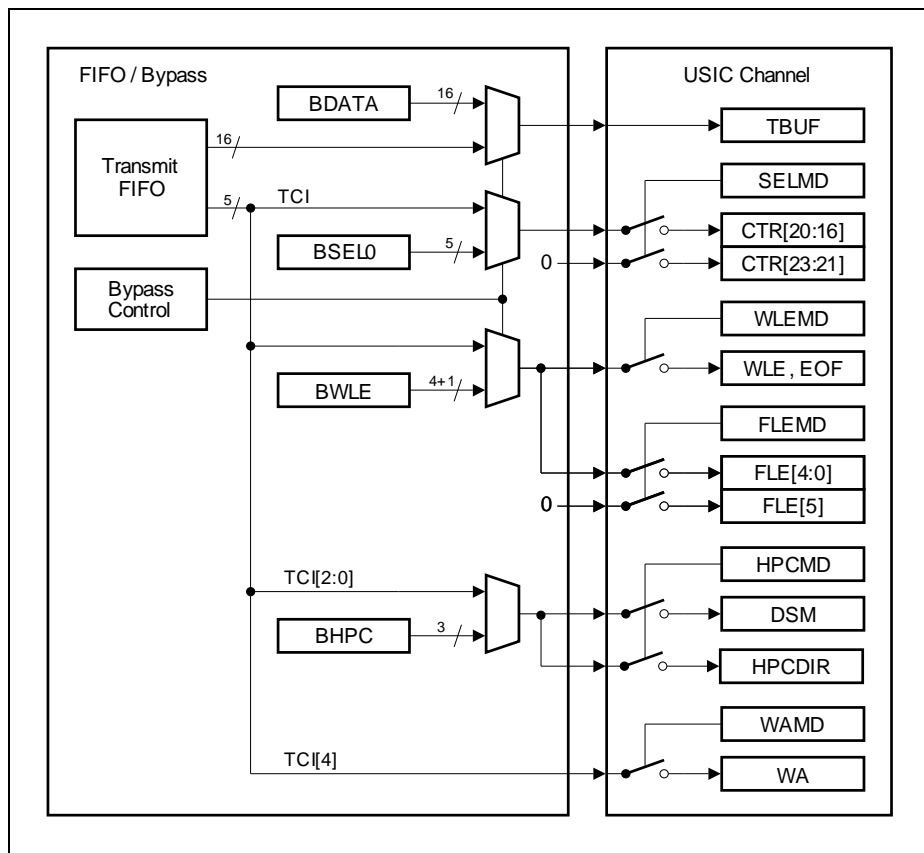

Figure 14-28 TCI Handling with FIFO / Bypass

Universal Serial Interface Channel (USIC)

14.3 Asynchronous Serial Channel (ASC = UART)

The asynchronous serial channel ASC covers the reception and the transmission of asynchronous data frames and provides a hardware LIN support. The receiver and transmitter being independent, frames can start at different points in time for transmission and reception. The ASC mode is selected by $CCR.MODE = 0010_B$ with $CCFG.ASC = 1$ (ASC mode available).

14.3.1 Signal Description

An ASC connection is characterized by the use of a single connection line between a transmitter and a receiver. The receiver input RXD signal is handled by the input stage DX0.

Figure 14-29 ASC Signal Connections for Full-Duplex Communication

For full-duplex communication, an independent communication line is needed for each transfer direction. **Figure 14-29** shows an example with a point-to-point full-duplex connection between two communication partners ASC A and ASC B.

For half-duplex or multi-transmitter communication, a single communication line is shared between the communication partners. **Figure 14-30** shows an example with a point-to-point half-duplex connection between ASC A and ASC B. In this case, the user has to take care that only one transmitter is active at a time. In order to support transmitter collision detection, the input stage DX1 can be used to monitor the level of the transmit line and to check if the line is in the idle state or if a collision occurred. There are two possibilities to connect the receiver input DIN0 to the transmitter output

Universal Serial Interface Channel (USIC)

DOUT0. Communication partner ASC A uses an internal connection with only the transmit pin TXD, that is delivering its input value as RXD to the DX0 input stage for reception and to DX1 to check for transmitter collisions. Communication partner ASC B uses an external connection between the two pins TXD and RXD.

Figure 14-30 ASC Signal Connections for Half-Duplex Communication

14.3.2 Frame Format

A standard ASC frame is shown in [Figure 14-31](#). It consists of:

- An idle time with the signal level 1.
- One start of frame bit (SOF) with the signal level 0.
- A data field containing a programmable number of data bits (1-63).
- A parity bit (P), programmable for either even or odd parity. It is optionally possible to handle frames without parity bit.
- One or two stop bits with the signal level 1.

Figure 14-31 Standard ASC Frame Format

The protocol specific bits (SOF, P, STOP) are automatically handled by the ASC protocol state machine and do not appear in the data flow via the receive and transmit buffers.

14.3.2.1 Idle Time

The receiver and the transmitter independently check the respective data input lines (DX0, DX1) for being idle. The idle detection ensures that an SOF bit of a recently enabled ASC module does not collide with an already running frame of another ASC module.

In order to start the idle detection, the user software has to clear bits PSR.RXIDLE and/or PSR.TXIDLE, e.g. before selecting the ASC mode or during operation. If a bit is cleared by software while a data transfer is in progress, the currently running frame transfer is finished normally before starting the idle detection again. Frame reception is only possible if PSR.RXIDLE = 1 and frame transmission is only possible if PSR.TXIDLE = 1. The duration of the idle detection depends on the setting of bit PCR.IDM. In the case that a collision is not possible, the duration can be shortened and the bus can be declared as being idle by setting PCR.IDM = 0.

In the case that the complete idle detection is enabled by PCR.IDM = 1, the data input of DX0 is considered as idle (PSR.RXIDLE becomes set) if a certain number of consecutive passive bit times has been detected. The same scheme applies for the transmitter's data input of DX1. Here, bit PSR.TXIDLE becomes set if the idle condition of this input signal has been detected.

The duration of the complete idle detection is given by the number of programmed data bits per frame plus 2 (in the case without parity) or plus 3 (in the case with parity). The counting of consecutive bit times with 1 level restarts from the beginning each time an edge is found, after leaving a stop mode or if ASC mode becomes enabled.

If the idle detection bits PSR.RXIDLE and/or TXIDLE are cleared by software, the counting scheme is not stopped (no re-start from the beginning). As a result, the cleared bit(s) can become set immediately again if the respective input line still meets the idle criterion.

Please note that the idle time check is based on bit times, so the maximum time can be up to 1 bit time more than programmed value (but not less).

14.3.2.2 Start Bit Detection

The receiver input signal DIN0 (selected signal of input stage DX0) is checked for a falling edge. An SOF bit is detected when a falling edge occurs while the receiver is idle or after the sampling point of the last stop bit. To increase noise immunity, the SOF bit timing starts with the first falling edge that is detected. If the sampled bit value of the SOF is 1, the previous falling edge is considered to be due to noise and the receiver is considered to be idle again.

14.3.2.3 Data Field

The length of the data field (number of data bits) can be programmed by bit field SCTR.FLE. It can vary between 1 and 63 data bits, corresponding to values of SCTR.FLE = 0 to 62 (the value of 63 is reserved and must not be programmed in ASC mode).

The data field can consist of several data words, e.g. a transfer of 12 data bits can be composed of two 8-bit words, with the 12 bits being split into 8-bits of the first word and 4 bits of the second word. The user software has to take care that the transmit data is available in-time, once a frame has been started. If the transmit buffer runs empty during a running data frame, the passive data level (SCTR.PDL) is sent out.

The shift direction can be programmed by SCTR.SDIR. The standard setting for ASC frames with LSB first is achieved with the default setting SDIR = 0.

14.3.2.4 Parity Bit

The ASC allows parity generation for transmission and parity check for reception on frame base. The type of parity can be selected by bit field CCR.PM, common for transmission and reception (no parity, even or odd parity). If the parity handling is disabled, the ASC frame does not contain any parity bit. For consistency reasons, all communication partners have to be programmed to the same parity mode.

After the last data bit of the data field, the transmitter automatically sends out its calculated parity bit if parity generation has been enabled. The receiver interprets this bit as received parity and compares it to its internally calculated one. The received parity bit value and the result of the parity check are monitored in the receiver buffer status registers, RBUFSR and RBUF01SR, as receiver buffer status information. These registers contain bits to monitor a protocol-related argument (PAR) and protocol-related error indication (PERR).

14.3.2.5 Stop Bit(s)

Each ASC frame is completed by 1 or 2 of stop bits with the signal level 1 (same level as the idle level). The number of stop bits is programmable by bit PSR.STPB. A new start bit can be transferred directly after the last stop bit.

14.3.3 Operating the ASC

In order to operate the ASC protocol, the following issues have to be considered:

- **Select ASC mode:**
 It is recommended to configure all parameters of the ASC that do not change during run time while $CCR.MODE = 0000_B$. Bit field $SCTR.TRM = 01_B$ has to be programmed. The configuration of the input stages has to be done while $CCR.MODE = 0000_B$ to avoid unintended edges of the input signals and the ASC mode can be enabled by $CCR.MODE = 0010_B$ afterwards.
- **Pin connections:**
 Establish a connection of input stage DX0 with the selected receive data input pin (signal DIN0) with $DX0CR.INSW = 0$ and configure a transmit data output pin (signal DOUT0). For collision or idle detection of the transmitter, the input stage DX1 has to be connected to the selected transmit output pin, also with $DX1CR.INSW = 0$. Additionally, program $DX2CR.INSW = 0$.
 Due to the handling of the input data stream by the synchronous protocol handler, the propagation delay of the synchronization in the input stage has to be considered.
 Note that the step to enable the alternate output port functions should only be done after the ASC mode is enabled, to avoid unintended spikes on the output.
- **Bit timing configuration:**
 The desired baud rate setting has to be selected, comprising the fractional divider, the baud rate generator and the bit timing. Please note that not all feature combinations can be supported by the application at the same time, e.g. due to propagation delays. For example, the length of a frame is limited by the frequency difference of the transmitter and the receiver device. Furthermore, in order to use the average of samples ($SMD = 1$), the sampling point has to be chosen to respect the signal settling and data propagation times.
- **Data format configuration:**
 The word length, the frame length, and the shift direction have to be set up according to the application requirements by programming the register SCTR. If required by the application, the data input and output signals can be inverted.
 Additionally, the parity mode has to be configured ($CCR.PM$).

14.3.3.1 Bit Timing

In ASC mode, each bit (incl. protocol bits) is divided into time quanta in order to provide granularity in the sub-bit range to adjust the sample point to the application requirements. The number of time quanta per bit is defined by bit fields $BRG.DCTQ$ and the length of a time quantum is given by $BRG.PCTQ$.

In the example given in [Figure 14-32](#), one bit time is composed of 16 time quanta ($BRG.DCTQ = 15$). It is not recommended to program less than 4 time quanta per bit time.

Universal Serial Interface Channel (USIC)

Bit field PCR.SP determines the position of the sampling point for the bit value. The value of PCR.SP must not be set to a value greater than BRG.DCTQ. It is possible to sample the bit value only once per bit time or to take the average of samples. Depending on bit PCR.SMD, either the current input value is directly sampled as bit value, or a majority decision over the input values sampled at the latest three time quanta is taken into account. The standard ASC bit timing consists of 16 time quanta with sampling after 8 or 9 time quanta with majority decision.

The bit timing setup (number of time quanta and the sampling point definition) is common for the transmitter and the receiver. Due to independent bit timing blocks, the receiver and the transmitter can be in different time quanta or bit positions inside their frames. The transmission of a frame is aligned to the time quanta generation.

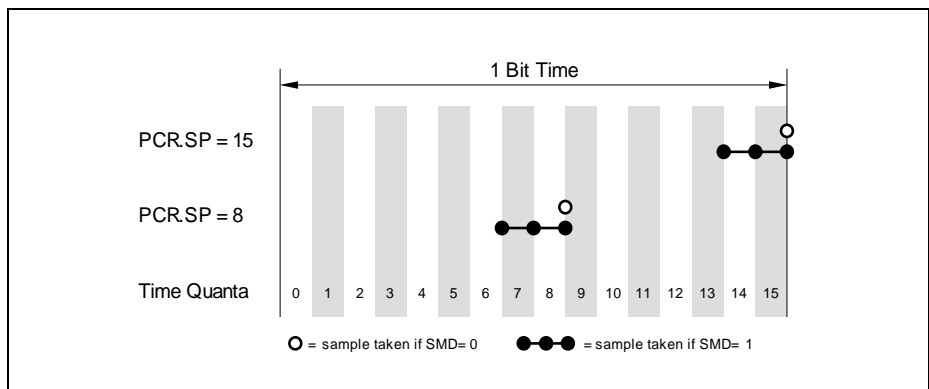

Figure 14-32 ASC Bit Timing

The sample point setting has to be adjusted carefully if collision or idle detection is enabled (via DX1 input signal), because the driver delay and some external delays have to be taken into account. The sample point for the transmit line has to be set to a value where the bit level is stable enough to be evaluated.

If the sample point is located late in the bit time, the signal itself has more time to become stable, but the robustness against differences in the clock frequency of transmitter and receiver decreases.

14.3.3.2 Baud Rate Generation

The baud rate f_{ASC} in ASC mode depends on the number of time quanta per bit time and their timing. The baud rate setting should only be changed while the transmitter and the receiver are idle. The bits in register BRG define the baud rate setting:

- **BRG.CTQSEL**
to define the input frequency f_{CTQIN} for the time quanta generation

Universal Serial Interface Channel (USIC)

- **BRG.PCTQ**
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4)
- **BRG.DCTQ**
to define the number of time quanta per bit time

The standard setting is given by $\text{CTQSEL} = 00_{\text{B}}$ ($f_{\text{CTQIN}} = f_{\text{PDIV}}$) and $\text{PPPEN} = 0$ ($f_{\text{PPP}} = f_{\text{PIN}}$). Under these conditions, the baud rate is given by:

$$f_{\text{ASC}} = f_{\text{PIN}} \times \frac{1}{\text{PDIV} + 1} \times \frac{1}{\text{PCTQ} + 1} \times \frac{1}{\text{DCTQ} + 1} \quad (14.6)$$

In order to generate slower frequencies, two additional divide-by-2 stages can be selected by $\text{CTQSEL} = 10_{\text{B}}$ ($f_{\text{CTQIN}} = f_{\text{SCLK}}$) and $\text{PPPEN} = 1$ ($f_{\text{PPP}} = f_{\text{MCLK}}$), leading to:

$$f_{\text{ASC}} = \frac{f_{\text{PIN}}}{2 \times 2} \times \frac{1}{\text{PDIV} + 1} \times \frac{1}{\text{PCTQ} + 1} \times \frac{1}{\text{DCTQ} + 1} \quad (14.7)$$

14.3.3.3 Noise Detection

The ASC receiver permanently checks the data input line of the DX0 stage for noise (the check is independent from the setting of bit PCR.SMD). Bit PSR.RNS (receiver noise) becomes set if the three input samples of the majority decision are not identical at the sample point for the bit value. The information about receiver noise gets accumulated over several bits in bit PSR.RNS (it has to be cleared by software) and can trigger a protocol interrupt each time noise is detected if enabled by PCR.RNIEN .

14.3.3.4 Collision Detection

In some applications, such as data transfer over a single data line shared by several sending devices (see [Figure 14-30](#)), several transmitters have the possibility to send on the same data output line TXD. In order to avoid collisions of transmitters being active at the same time or to allow a kind of arbitration, a collision detection has been implemented.

The data value read at the TXD input at the DX1 stage and the transmitted data bit value are compared after the sampling of each bit value. If enabled by $\text{PCR.CDEN} = 1$ and a bit sent is not equal to the bit read back, a collision is detected and bit PSR.COL is set. If enabled, bit $\text{PSR.COL} = 1$ disables the transmitter (the data output lines become 1) and generates a protocol interrupt. The content of the transmit shift register is considered as invalid, so the transmit buffer has to be programmed again.

14.3.3.5 Pulse Shaping

For some applications, the 0 level of transmitted bits with the bit value 0 is not applied at the transmit output during the complete bit time. Instead of driving the original 0 level,

Universal Serial Interface Channel (USIC)

only a 0 pulse is generated and the remaining time quanta of the bit time are driven with 1 level. The length of a bit time is not changed by the pulse shaping, only the signalling is changed.

In the standard ASC signalling scheme, the 0 level is signalled during the complete bit time with bit value 0 (ensured by programming $\text{PCR.PL} = 000_{\text{B}}$). In the case $\text{PCR.PL} > 000_{\text{B}}$, the transmit output signal becomes 0 for the number of time quanta defined by PCR.PL . In order to support correct reception with pulse shaping by the transmitter, the sample point has to be adjusted in the receiver according to the applied pulse length.

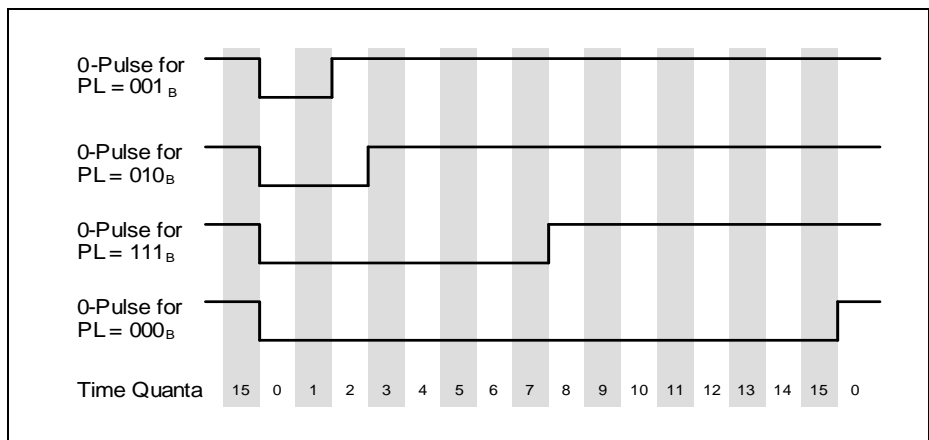

Figure 14-33 Transmitter Pulse Length Control

Figure 14-34 shows an example for the transmission of an 8-bit data word with LSB first and one stop bit (e.g. like for IrDA). The polarity of the transmit output signal has been inverted by $\text{SCTR.DOCFG} = 01_{\text{B}}$.

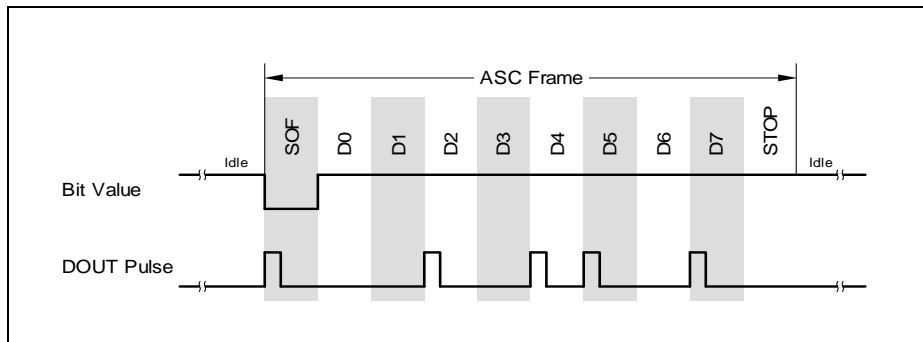

Figure 14-34 Pulse Output Example

14.3.3.6 Automatic Shadow Mechanism

The contents of the protocol control register PCR, as well as bit field SCTR.FLE are internally kept constant while a data frame is transferred by an automatic shadow mechanism (shadowing takes place with each frame start). The registers can be programmed all the time with new settings that are taken into account for the next data frame. During a data frame, the applied (shadowed) setting is not changed, although new values have been written after the start of the data frame.

Bit fields SCTR.WLE and SCTR.SDIR are shadowed automatically with the start of each data word. As a result, a data frame can consist of data words with a different length. It is recommended to change SCTR.SDIR only when no data frame is running to avoid interference between hardware and software.

Please note that the starting point of a data word can be different for a transmitter and a receiver. In order to ensure correct handling, it is recommended to modify SCTR.WLE only while transmitter and receiver are both idle. If the transmitter and the receiver are referring to the same data signal (e.g. in a LIN bus system), SCTR.WLE can be modified while a data transfer is in progress after the RSI event has been detected.

14.3.3.7 End of Frame Control

The number of bits per ASC frame is defined by bit field SCTR.FLE. In order to support different frame length settings for consecutively transmitted frames, this bit field can be modified by hardware. The automatic update mechanism is enabled by TCSR.FLEMD = 1 (in this case, bits TCSR.WLEMD, SELMD, WAMD and HPCMD have to be written with 0).

If enabled, the transmit control information TCI automatically overwrites the bit field TCSR.FLEMD when the ASC frame is started (leading to frames with 1 to 32 data bits). The TCI value represents the written address location of TBUFxx (without additional data

Universal Serial Interface Channel (USIC)

buffer) or INxx (with additional data buffer). With this mechanism, an ASC with 8 data bits is generated by writing a data word to TBUF07 (IN07, respectively).

14.3.3.8 Mode Control Behavior

In ASC mode, the following kernel modes are supported:

- Run Mode 0/1:
Behavior as programmed, no impact on data transfers.
- Stop Mode 0:
Bit PSR.TXIDLE is cleared. A new transmission is not started. A current transmission is finished normally. Bit PSR.RXIDLE is not modified. Reception is still possible. When leaving stop mode 0, bit TXIDLE is set according to PCR.IDM.
- Stop Mode 1:
Bit PSR.TXIDLE is cleared. A new transmission is not started. A current transmission is finished normally. Bit PSR.RXIDLE is cleared. A new reception is not possible. A current reception is finished normally. When leaving stop mode 1, bits TXIDLE and RXIDLE are set according to PCR.IDM.

14.3.3.9 Disabling ASC Mode

In order to switch off ASC mode without any data corruption, the receiver and the transmitter have to be both idle. This is ensured by requesting Stop Mode 1 in register KSCFG. After waiting for the end of the frame, the ASC mode can be disabled.

14.3.3.10 Protocol Interrupt Events

The following protocol-related events are generated in ASC mode and can lead to a protocol interrupt. The collision detection and the transmitter frame finished events are related to the transmitter, whereas the receiver events are given by the synchronization break detection, the receiver noise detection, the format error checks and the end of the received frame.

Please note that the bits in register PSR are not automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- Collision detection:
This interrupt indicates that the transmitted value (DOUT0) does not match with the input value of the DX1 input stage at the sample point of a bit. For more details refer to [Page 14-60](#).
- Transmitter frame finished:
This interrupt indicates that the transmitter has completely finished a frame. Bit PSR.TFF becomes set at the end of the last stop bit. The DOUT0 signal assignment to port pins can be changed while no transmission is in progress.
- Receiver frame finished:
This interrupt indicates that the receiver has completely finished a frame. Bit

Universal Serial Interface Channel (USIC)

PSR.RFF becomes set at the end of the last stop bit. The DIN0 signal assignment to port pins can be changed while no reception is in progress.

- Synchronization break detection:
This interrupt can be used in LIN networks to indicate the reception of the synchronization break symbol (at the beginning of a LIN frame).
- Receiver noise detection:
This interrupt indicates that the input value at the sample point of a bit and at the two time quanta before are not identical.
- Format error:
The bit value of the stop bit(s) is defined as 1 level for the ASC protocol. A format error is signalled if the sampled bit value of a stop bit is 0.

14.3.3.11 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to ASC frame handling.

- Transmit buffer interrupt TBI:
Bit PSR.TBIF is set after the start of first data bit of a data word. This is the earliest point in time when a new data word can be written to TBUF.
With this event, bit TCSR.TDV is cleared and new data can be loaded to the transmit buffer.
- Transmit shift interrupt TSI:
Bit PSR.TSIF is set after the start of the last data bit of a data word.
- Receiver start interrupt RSI:
Bit PSR.RSIF is set after the sample point of the first data bit of a data word.
- Receiver interrupt RI and alternative interrupt AI:
Bit PSR.RIF is set after the sampling point of the last data bit of a data word if this data word is not directly followed by a parity bit (parity generation disabled or not the last word of a data frame).
If the data word is directly followed by a parity bit (last data word of a data frame and parity generation enabled), bit PSR.RIF is set after the sampling point of the parity bit if no parity error has been detected. If a parity error has been detected, bit PSR.AIF is set instead of bit PSR.RIF.
The first data word of a data frame is indicated by RBUFSR.SOF = 1 for the received word.
Bit PSR.RIF is set for a receiver interrupt RI with WA = 0. Bit PSR.AIF is set for a alternative interrupt AI with WA = 1.

14.3.3.12 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

14.3.3.13 Protocol-Related Argument and Error

The protocol-related argument (RBUFSR.PAR) and the protocol-related error (RBUFSR.PERR) are two flags that are assigned to each received data word in the corresponding receiver buffer status registers.

In ASC mode, the received parity bit is monitored by the protocol-related argument and the result of the parity check by the protocol-related error indication (0 = received parity bit equal to calculated parity value). This information being elaborated only for the last received data word of each data frame, both bit positions are 0 for data words that are not the last data word of a data frame or if the parity generation is disabled.

14.3.3.14 Receive Buffer Handling

If a receive FIFO buffer is available (CCFG.RB = 1) and enabled for data handling (RBCTR.SIZE > 0), it is recommended to set RBCTR.RCIM = 11_B in ASC mode. This leads to an indication that the data word has been the first data word of a new data frame if bit OUTR.RCI[0] = 1, a parity error is indicated by OUTR.RCI[4] = 1, and the received parity bit value is given by OUTR.RCI[3].

The standard receive buffer event and the alternative receive buffer event can be used for the following operations in RCI mode (RBCTR.RNM = 1):

- A standard receive buffer event indicates that a data word can be read from OUTR that has been received without parity error.
- An alternative receive buffer event indicates that a data word can be read from OUTR that has been received with parity error.

14.3.3.15 Sync-Break Detection

The receiver permanently checks the DIN0 signal for a certain number of consecutive bit times with 0 level. The number is given by the number of programmed bits per frame (SCTR.FLE) plus 2 (in the case without parity) or plus 3 (in the case with parity). If a 0 level is detected at a sample point of a bit after this event has been found, bit PSR.SBD is set and additionally, a protocol interrupt can be generated (if enabled by PCR.SBIEN = 1). The counting restarts from 0 each time a falling edge is found at input DIN0. This feature can be used for the detection of a synchronization break for slave devices in a LIN bus system (the master does not check for sync break).

For example, in a configuration for 8 data bits without parity generation, bit PCR.SBD is set after at the next sample point at 0 level after 10 complete bit times have elapsed (representing the sample point of the 11th bit time since the first falling edge).

14.3.3.16 Transfer Status Indication

The receiver status can be monitored by flag PSR[9] = BUSY if bit PCR.CTR[16] (receiver status enable RSTEN) is set. In this case, bit BUSY is set during a complete frame reception from the beginning of the start of frame bit to the end of the last stop bit.

Universal Serial Interface Channel (USIC)

The transmitter status can be monitored by flag PSR[9] = BUSY if bit PCR.CTR[17] (transmitter status enable TSTEN) is set. In this case, bit BUSY is set during a complete frame reception from the beginning of the start of frame bit to the end of the last stop bit. If both bits RSTEN and TSTEN are set, flag BUSY indicates the logical OR-combination of the receiver and the transmitter status. If both bits are cleared, flag BUSY is not modified depending on the transfer status (status changes are ignored).

14.3.4 ASC Protocol Registers

In ASC mode, the registers PCR and PSR handle ASC related information.

14.3.4.1 ASC Protocol Control Register

In ASC mode, the PCR register bits or bit fields are defined as described in this section.

PCR

Protocol Control Register [ASC Mode]

(3C_H)

| rw | | | rw | | | | rw | rw | rw | rw | rw | rw | rw | rw | |

| Field | Bits | Type | Description |
|-------|------|------|--|
| SMD | 0 | rw | Sample Mode This bit field defines the sample mode of the ASC receiver. The selected data input signal can be sampled only once per bit time or three times (in consecutive time quanta). When sampling three times, the bit value shifted in the receiver shift register is given by a majority decision among the three sampled values. 0 _B Only one sample is taken per bit time. The current input value is sampled. 1 _B Three samples are taken per bit time and a majority decision is made. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| STPB | 1 | rw | Stop Bits This bit defines the number of stop bits in an ASC frame. 0 _B The number of stop bits is 1. 1 _B The number of stop bits is 2. |
| IDM | 2 | rw | Idle Detection Mode This bit defines if the idle detection is switched off or based on the frame length. 0 _B The bus idle detection is switched off and bits PSR.TXIDLE and PSR.RXIDLE are set automatically to enable data transfers without checking the inputs before. 1 _B The bus is considered as idle after a number of consecutive passive bit times defined by SCTR.FLE plus 2 (in the case without parity bit) or plus 3 (in the case with parity bit). |
| SBIEN | 3 | rw | Synchronization Break Interrupt Enable This bit enables the generation of a protocol interrupt if a synchronization break is detected. The automatic detection is always active, so bit SBD can be set independently of SBIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |
| CDEN | 4 | rw | Collision Detection Enable This bit enables the reaction of a transmitter to the collision detection. 0 _B The collision detection is disabled. 1 _B If a collision is detected, the transmitter stops its data transmission, outputs a 1, sets bit PSR.COL and generates a protocol interrupt. In order to allow data transmission again, PSR.COL has to be cleared by software. |
| RNIEN | 5 | rw | Receiver Noise Detection Interrupt Enable This bit enables the generation of a protocol interrupt if receiver noise is detected. The automatic detection is always active, so bit PSR.RNS can be set independently of PCR.RNIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| FEIEN | 6 | rw | Format Error Interrupt Enable This bit enables the generation of a protocol interrupt if a format error is detected. The automatic detection is always active, so bits PSR.FER0/FER1 can be set independently of PCR.FEIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |
| FFIEN | 7 | rw | Frame Finished Interrupt Enable This bit enables the generation of a protocol interrupt if the receiver or the transmitter reach the end of a frame. The automatic detection is always active, so bits PSR.RFF or PSR.TFF can be set independently of PCR.FFIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |
| SP | [12:8] | rw | Sample Point This bit field defines the sample point of the bit value. The sample point must not be located outside the programmed bit timing ($PCR.SP \leq BRG.DCTQ$). |
| PL | [15:13] | rw | Pulse Length This bit field defines the length of a 0 data bit, counted in time quanta, starting with the time quantum 0 of each bit time. Each bit value that is a 0 can lead to a 0 pulse that is shorter than a bit time, e.g. for IrDA applications. The length of a bit time is not changed by PL, only the length of the 0 at the output signal. The pulse length must not be longer than the programmed bit timing ($PCR.PL \leq BRG.DCTQ$). This bit field is only taken into account by the transmitter and is ignored by the receiver. 000 _B The pulse length is equal to the bit length (no shortened 0). 001 _B The pulse length of a 0 bit is 2 time quanta. 010 _B The pulse length of a 0 bit is 3 time quanta. ... 111 _B The pulse length of a 0 bit is 8 time quanta. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| RSTEN | 16 | rw | Receiver Status Enable This bit enables the modification of flag PSR[9] = BUSY according to the receiver status. 0 _B Flag PSR[9] is not modified depending on the receiver status. 1 _B Flag PSR[9] is set during the complete reception of a frame. |
| TSTEN | 17 | rw | Transmitter Status Enable This bit enables the modification of flag PSR[9] = BUSY according to the transmitter status. 0 _B Flag PSR[9] is not modified depending on the transmitter status. 1 _B Flag PSR[9] is set during the complete transmission of a frame. |
| MCLK | 31 | rw | Master Clock Enable This bit enables the generation of the master clock MCLK. 0 _B The MCLK generation is disabled and the MCLK signal is 0. 1 _B The MCLK generation is enabled. |
| 0 | [30:18] | r | Reserved Returns 0 if read; should be written with 0. |

14.3.4.2 ASC Protocol Status Register

In ASC mode, the PSR register bits or bit fields are defined as described in this section. The bits and bit fields in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. The PSR flags should be cleared by software before enabling a new protocol.

Universal Serial Interface Channel (USIC)

| TBIF | 13 | rwh | Transmit Buffer Indication Flag 0_B A transmit buffer event has not occurred. 1_B A transmit buffer event has occurred. |
| RIF | 14 | rwh | Receive Indication Flag 0_B A receive event has not occurred. 1_B A receive event has occurred. |
| AIF | 15 | rwh | Alternative Receive Indication Flag 0_B An alternative receive event has not occurred. 1_B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0_B A baud rate generator event has not occurred. 1_B A baud rate generator event has occurred. |
| 0 | [31:17]] | r | Reserved Returns 0 if read; should be written with 0. |

1) This status bit can generate a protocol interrupt (see [Page 14-22](#)). The general interrupt status flags are described in the general interrupt chapter.

14.3.5 Hardware LIN Support

In order to support the LIN protocol, bit TCSR.FLEMD = 1 should be set for the master. For slave devices, it can be cleared and the fixed number of 8 data bits has to be set (SCTR.FLE = 7_H). For both, master and slave devices, the parity generation has to be switched off (CCR.PM = 00_B) and transfers take place with LSB first (SCTR.SDIR = 0) and 1 stop bit (PCR.STPB = 0).

The Local Interconnect Network (LIN) data exchange protocol contains several symbols that can all be handled in ASC mode. Each single LIN symbol represents a complete ASC frame. The LIN bus is a master-slave bus system with a single master and multiple slaves (for the exact definition please refer to the official LIN specification).

A complete LIN frame contains the following symbols:

- Synchronization break:

The master sends a synchronization break to signal the beginning of a new frame. It contains at least 13 consecutive bit times at 0 level, followed by at least one bit time at 1 level (corresponding to 1 stop bit). Therefore, TBUF11 if the transmit buffer is used, (or IN11 if the FIFO buffer is used) has to be written with 0 (leading to a frame with SOF followed by 12 data bits at 0 level).

A slave device shall detect 11 consecutive bit times at 0 level, which done by the synchronization break detection. Bit PSR.SBD is set if such an event is detected and a protocol interrupt can be generated. Additionally, the received data value of 0 appears in the receive buffer and a format error is signaled.

Universal Serial Interface Channel (USIC)

If the baud rate of the slave has to be adapted to the master, the baud rate measurement has to be enabled for falling edges by setting $BRG.TMEN = 1$, $DX0CR.CM = 10_H$ and $DX1CR.CM = 00_H$ before the next symbol starts.

- Synchronization byte:
The master sends this symbol after writing the data value 55_H to TBUF07 (or IN07). A slave device can either receive this symbol without any further action (and can discard it) or it can use the falling edges for baud rate measurement. Bit $PSR.TSIF = 1$ (with optionally the corresponding interrupt) indicates the detection of a falling edge and the capturing of the elapsed time since the last falling edge in $CMTR.CTV$. Valid captured values can be read out after the second, third, fourth and fifth activation of $TSIF$. After the fifth activation of $TSIF$ within this symbol, the baud rate detection can be disabled ($BRG.TMEN = 0$) and $BRG.PDIV$ can be programmed with the captured $CMTR.CTV$ value divided by twice the number of time quanta per bit (assuming $BRG.PCTQ = 00_B$).
- Other symbols:
The other symbols of a LIN frame can be handled with ASC data frames without specific actions.

If LIN frames should be sent out on a frame base by the LIN master, the input $DX2$ can be connected to external timers to trigger the transmit actions (e.g. the synchronization break symbol has been prepared but is started if a trigger occurs). Please note that during the baud rate measurement of the ASC receiver, the ASC transmitter of the same USIC channel can still perform a transmission.

14.4 Synchronous Serial Channel (SSC)

The synchronous serial channel SSC covers the data transfer function of an SPI-like module. It can handle reception and transmission of synchronous data frames between a device operating in master mode and at least one device in slave mode. Besides the standard SSC protocol consisting of one input and one output data line, SSC protocols with two (Dual-SSC) or four (Quad-SSC) input/output data lines are also supported. The SSC mode is selected by $CCR.MODE = 0001_B$ with $CCFG.SSC = 1$ (SSC mode is available).

14.4.1 Signal Description

A synchronous SSC data transfer is characterized by a simultaneous transfer of a shift clock signal together with the transmit and/or receive data signal(s) to determine when the data is valid (definition of transmit and sample point).

Figure 14-35 SSC Signals for Standard Full-Duplex Communication

In order to explicitly indicate the start and the end of a data transfer and to address more than one slave devices individually, the SSC module supports the handling of slave select signals. They are optional and are not necessarily needed for SSC data transfers. The SSC module supports up to 8 different slave select output signals for master mode operation (named $SELOx$, with $x = 0-7$) and 1 slave select input $SELIN$ for slave mode. In most applications, the slave select signals are active low.

Universal Serial Interface Channel (USIC)

A device operating in master mode controls the start and end of a data frame, as well as the generation of the shift clock and slave select signals. This comprises the baud rate setting for the shift clock and the delays between the shift clock and the slave select output signals. If several SSC modules are connected together, there can be only one SSC master at a time, but several slaves. Slave devices receive the shift clock and optionally a slave select signal(s). For the programming of the input stages DXn please refer to [Page 14-22](#).

Table 14-12 SSC Communication Signals

| SSC Mode | Receive Data | Transmit Data | Shift Clock | Slave Select(s) |
|---------------------|---|--------------------------------------|---------------------------------|--------------------------------|
| Standard SSC Master | MRST ¹⁾ , input DIN0, handled by DX0 | MTSR ²⁾ , Output DOUT0 | Output SCLKOUT | Output(s) SELOx |
| Standard SSC Slave | MTSR, input DIN0, handled by DX0 | MRST, Output DOUT0 | Input SCLKIN, handled by DX1 | input SELIN, handled by DX2 |
| Dual-SSC Master | MRST[1:0], input DIN[1:0], handled by DX0 and DX3 | MTSR[1:0], Output DOUT[1:0] | Output SCLKOUT | Output(s) SELOx |
| Dual-SSC Slave | MTSR[1:0], input DIN[1:0], handled by DX0 and DX3 | MRST[1:0], Output DOUT[1:0] | Input SCLKIN, handled by DX1 | input SELIN, handled by DX2 |
| Quad-SSC Master | MRST[3:0], input DIN[3:0], handled by DX0, DX3, DX4 and DX5 | MTSR[3:0], Output DOUT[3:0] | Output SCLKOUT | Output(s) SELOx |
| Quad-SSC Slave | MTSR[3:0], input DIN[3:0], handled by DX0, DX3, DX4 and DX5 | MRST[3:0], Output DOUT[3:0] | Input SCLKIN, handled by DX1 | input SELIN, handled by DX2 |

1) MRST = master receive slave transmit, also known as MISO = master in slave out

2) MTSR = master transmit slave receive, also known as MOSI = master out slave in

Universal Serial Interface Channel (USIC)

Figure 14-36 4-Wire SSC Standard Communication Signals

14.4.1.1 Transmit and Receive Data Signals

In standard SSC half-duplex mode, a single data line is used, either for data transfer from the master to a slave or from a slave to the master. In this case, MRST and MTSR are connected together, one signal as input, the other one as output, depending on the data direction. The user software has to take care about the data direction to avoid data collision (e.g. by preparing dummy data of all 1s for transmission in case of a wired AND connection with open-drain drivers, by enabling/disabling push/pull output drivers or by switching pin direction with hardware port control enabled). In full-duplex mode, data transfers take place in parallel between the master device and a slave device via two independent data signals MTSR and MRST, as shown in [Figure 14-35](#).

The receive data input signal DIN0 is handled by the input stage DX0. In master mode (referring to MRST) as well as in slave mode (referring to MTSR), the data input signal DIN0 is taken from an input pin. The signal polarity of DOUT0 (data output) with respect to the data bit value can be configured in block DOCFG (data output configuration) by bit field SCTR.DOCFG.

Figure 14-37 SSC Data Signals

Universal Serial Interface Channel (USIC)

For dual- and quad-SSC modes that require multiple input and output data lines to be used, additional input stages, DINx and DOUTx signals need to be set up.

14.4.1.2 Shift Clock Signals

The shift clock signal is handled by the input stage DX1. In slave mode, the signal SCLKIN is received from an external master, so the DX1 stage has to be connected to an input pin. The input stage can invert the received input signal to adapt to the polarity of SCLKIN to the function of the data shift unit (data transmission on rising edges, data reception on falling edges).

In master mode, the shift clock is generated by the internal baud rate generator. The output signal SCLK of the baud rate generator is taken as shift clock input for the data shift unit. The internal signal SCLK is made available for external slave devices by signal SCLKOUT. For complete closed loop delay compensation in a slave mode, SCLKOUT can also take the transmit shift clock from the input stage DX1. The selection is done through the bit BRG.SCLKOSEL. See [Section 14.4.6.3](#).

Figure 14-38 SSC Shift Clock Signals

Due to the multitude of different SSC applications, in master mode, there are different ways to configure the shift clock output signal SCLKOUT with respect to SCLK. This is done in the block SCLKCFG (shift clock configuration) by bit field BRG.SCLKCFG, allowing 4 possible settings, as shown in [Figure 14-39](#).

- No delay, no polarity inversion (SCLKCFG = 00_b, SCLKOUT equals SCLK):
The inactive level of SCLKOUT is 0, while no data frame is transferred. The first data bit of a new data frame is transmitted with the first rising edge of SCLKOUT and the first data bit is received in with the first falling edge of SCLKOUT. The last data bit of a data frame is transmitted with the last rising clock edge of SCLKOUT and the last

Universal Serial Interface Channel (USIC)

data bit is received in with the last falling edge of SCLKOUT. This setting can be used in master and in slave mode. It corresponds to the behavior of the internal data shift unit.

- No delay, polarity inversion (SCLKCFG = 01_B):
 The inactive level of SCLKOUT is 1, while no data frame is transferred. The first data bit of a new data frame is transmitted with the first falling clock edge of SCLKOUT and the first data bit is received with the first rising edge of SCLKOUT. The last data bit of a data frame is transmitted with the last falling edge of SCLKOUT and the last data bit is received with the last rising edge of SCLKOUT.
 This setting can be used in master and in slave mode. For slave mode, bit field DX1CR.DPOL = 1_B has to be programmed.
- SCLKOUT is delayed by 1/2 shift clock period, no polarity inversion (SCLKCFG = 10_B):
 The inactive level of SCLKOUT is 0, while no data frame is transferred.
 The first data bit of a new data frame is transmitted 1/2 shift clock period before the first rising clock edge of SCLKOUT. Due to the delay, the next data bits seem to be transmitted with the falling edges of SCLKOUT. The last data bit of a data frame is transmitted 1/2 period of SCLKOUT before the last rising clock edge of SCLKOUT. The first data bit is received 1/2 shift clock period before the first falling edge of SCLKOUT. Due to the delay, the next data bits seem to be received with the rising edges of SCLKOUT. The last data bit is received 1/2 period of SCLKOUT before the last falling clock edge of SCLKOUT.
 This setting can be used only in master mode and not in slave mode (the connected slave has to provide the first data bit before the first SCLKOUT edge, e.g. as soon as it is addressed by its slave select).
- SCLKOUT is delayed by 1/2 shift clock period, polarity inversion (SCLKCFG = 11_B):
 The inactive level of SCLKOUT is 1, while no data frame is transferred.
 The first data bit of a new data frame is transmitted 1/2 shift clock period before the first falling clock edge of SCLKOUT. Due to the delay, the next data bits seem to be transmitted with the rising edges of SCLKOUT. The last data bit of a data frame is transmitted 1/2 period of SCLKOUT before the last falling clock edge of SCLKOUT. The first data bit is received 1/2 shift clock period before the first rising edge of SCLKOUT. Due to the delay, the next data bits seem to be received with the falling edges of SCLKOUT. The last data bit is received 1/2 period of SCLKOUT before the last rising clock edge of SCLKOUT.
 This setting can be used only in master mode and not in slave mode (the connected slave has to provide the first data bit before the first SCLKOUT edge, e.g. as soon as it is addressed by its slave select).

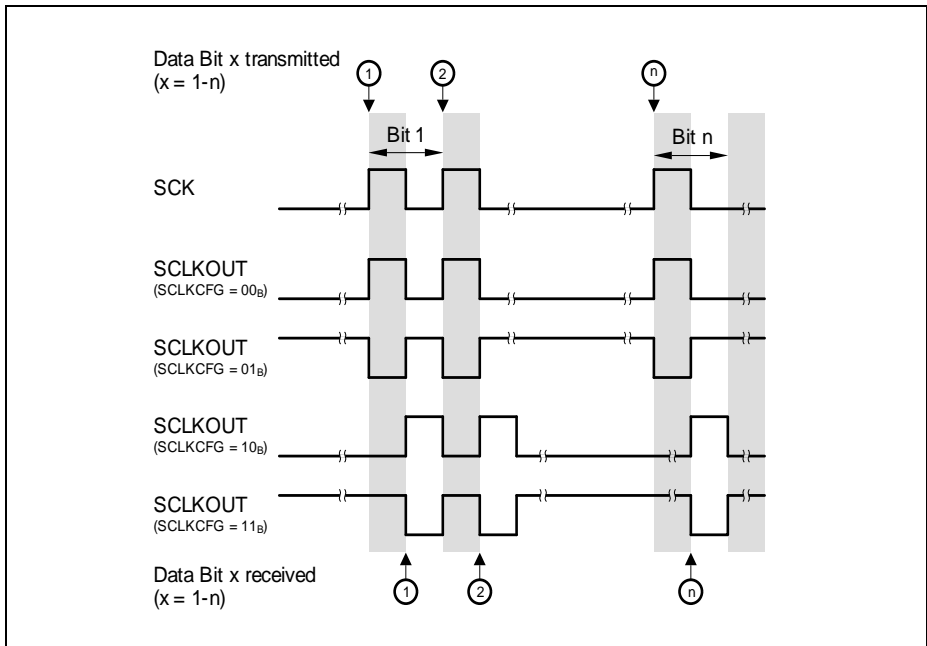

Figure 14-39 SCLKOUT Configuration in SSC Master Mode

Note: If a configuration with delay is selected and a slave select line is used, the slave select delays have to be set up accordingly.

In SSC slave mode, the bit PCR.SLPSEL can be used to configure the clock phase of the data shift.

- When SLPSEL = 0_B, the slave SSC transmits data bits with each leading edge of the selected shift clock input (SCLKIN) and receives data bits with each trailing edge of SCLKIN
- When SLPSEL = 1_B, the slave SSC transmits the first data bit once the selected slave select input (SELIN) becomes active. If SELIN is not used, the DX2 stage has to deliver a 1-level to the data shift unit to shift out the first bit. Subsequent data bits are then transmitted with each trailing edge of SCLKIN. The SSC slave receives all data bits with each leading edge of SCLKIN.

For both settings, the clock polarity is determined by bit 0 of SCLKCFG.

Universal Serial Interface Channel (USIC)

Figure 14-40 SLPHSEL Configuration in SSC Slave Mode

14.4.1.3 Slave Select Signals

The slave select signal is handled by the input stage DX2. In slave mode, the input signal SELIN is received from an external master via an input pin. The input stage can invert the received input signal to adapt the polarity of signal SELIN to the function of the data shift unit (the module internal signals are considered as high active, so a data transfer is only possible while the slave select input of the data shift unit is at 1-level, otherwise, shift clock pulses are ignored and do not lead to data transfers). If an input signal SELIN is low active, it should be inverted in the DX2 input stage.

In master mode, a master slave select signal MSLS is generated by the internal slave select generator. In order to address different external slave devices independently, the internal MSLS signal is made available externally via up to 8 SELOx output signals that can be configured by the block SELCFG (select configuration).

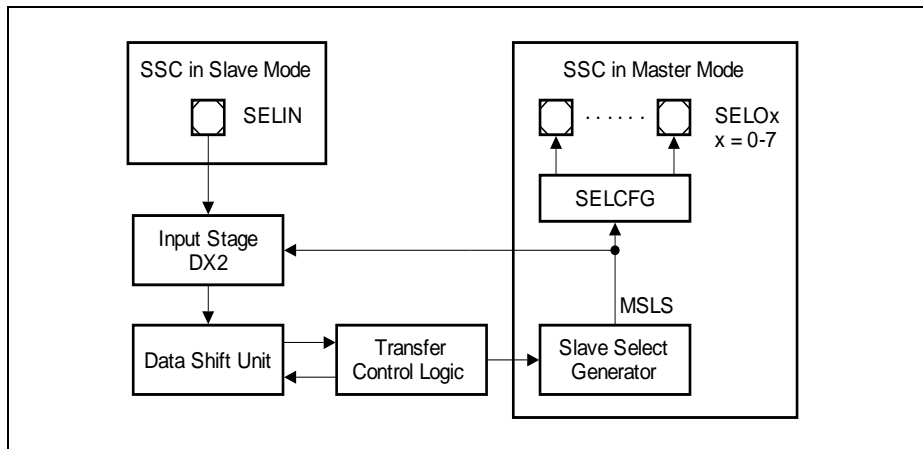

Figure 14-41 SSC Slave Select Signals

The control of the SELCFG block is based on protocol specific bits and bit fields in the protocol control register PCR. For the generation of the MSLS signal please refer to [Section 14.4.3.2](#).

- PCR.SELCTR to chose between direct and coded select mode
- PCR.SELINV to invert the SELOx outputs
- PCR.SELO[7:0] as individual value for each SELOx line

The SELCFG block supports the following configurations of the SELOx output signals:

- Direct Select Mode (SELCTR = 1):
Each SELOx line (with x = 0-7) can be directly connected to an external slave device. If bit x in bit field SELO is 0, the SELOx output is permanently inactive. A SELOx output becomes active while the internal signal MSLS is active (see [Section 14.4.3.2](#)) and bit x in bit field SELO is 1. Several external slave devices can be addressed in parallel if more than one bit in bit field SELO are set during a data frame. The number of external slave devices that can be addressed individually is limited to the number of available SELOx outputs.
- Coded Select Mode (SELCTR = 0):
The SELOx lines (with x = 1-7) can be used as addresses for an external address decoder to increase the number of external slave devices. These lines only change with the start of a new data frame and have no other relation to MSLS. Signal SELO0 can be used as enable signal for the external address decoder. It is active while MSLS is active (during a data frame) and bit 0 in bit field SELO is 1. Furthermore, in coded select mode, this output line is delayed by one cycle of f_{PERIPH} compared to MSLS to allow the other SELOx lines to stabilize before enabling the address decoder.

14.4.2 Operating the SSC

This chapter contains SSC issues, that are of general interest and not directly linked to either master mode or slave mode.

14.4.2.1 Automatic Shadow Mechanism

The contents of the baud rate control register BRG, bit fields SCTR.FLE as well as the protocol control register PCR are internally kept constant while a data frame is transferred (= while MSLS is active) by an automatic shadow mechanism. The registers can be programmed all the time with new settings that are taken into account for the next data frame. During a data frame, the applied (shadowed) setting is not changed, although new values have been written after the start of the data frame.

Bit fields SCTR.WLE, SCTR.DSM, SCTR.HPCDIR and SCTR.SDIR are shadowed automatically with the start of each data word. As a result, a data frame can consist of data words with a different length, or data words that are transmitted or received through different number of data lines. It is recommended to change SCTR.SDIR only when no data frame is running to avoid interference between hardware and software.

Please note that the starting point of a data word are different for a transmitter (first bit transmitted) and a receiver (first bit received). In order to ensure correct handling, it is recommended to refer to the receive start interrupt RSI before modifying SCTR.WLE. If TCSR.WLEMD = 1, it is recommended to update TCSR and TBUFxx after the receiver start interrupt has been generated.

14.4.2.2 Mode Control Behavior

In SSC mode, the following kernel modes are supported:

- Run Mode 0/1:
Behavior as programmed, no impact on data transfers.
- Stop Mode 0/1:
The content of the transmit buffer is considered as not valid for transmission. Although being considered as 0, bit TCSR.TDV it is not modified by the stop mode condition.
In master mode, a currently running word transfer is finished normally, but no new data word is started (the stop condition is not considered as end-of-frame condition).
In slave mode, a currently running word transfer is finished normally. Passive data will be sent out instead of a valid data word if a data word transfer is started by the external master while the slave device is in stop mode. In order to avoid passive slave transmit data, it is recommended not to program stop mode for an SSC slave device if the master device does not respect the slave device's stop mode.

14.4.2.3 Disabling SSC Mode

In order to disable SSC mode without any data corruption, the receiver and the transmitter have to be both idle. This is ensured by requesting Stop Mode 1 in register KSCFG. After Stop Mode 1 has been acknowledged by KSCFG.2 = 1, the SSC mode can be disabled.

14.4.2.4 Data Frame Control

An SSC data frame can consist of several consecutive data words that may be separated by an inter-word delay. Without inter-word delay, the data words seem to form a longer data word, being equivalent to a data frame. The length of the data words are most commonly identical within a data frame, but may also differ from one word to another. The data word length information (defined by SCTR.WLE) is evaluated for each new data word, whereas the frame length information (defined by SCTR.FLE) is evaluated at the beginning at each start of a new frame.

The length of an SSC data frame can be defined in two different ways:

- By the number of bits per frame:
If the number of bits per data frame is defined (frame length FLE), a slave select signal is not necessarily required to indicate the start and the end of a data frame.
If the programmed number of bits per frame is reached within a data word, the frame is considered as finished and remaining data bits in the last data word are ignored and are not transferred.
This method can be applied for data frames with up to 63 data bits.
- By the slave select signal:
If the number of bits per data frame is not known, the start/end information of a data frame is given by a slave select signal. If a deactivation of the slave select signal is detected within a data word, the frame is considered as finished and remaining data bits in the last data word are ignored and are not transferred.
This method has to be applied for frames with more than 63 data bits (programming limit of FLE). The advantage of slave select signals is the clearly defined start and end condition of data frames in a data stream. Furthermore, slave select signals allow to address slave devices individually.

14.4.2.5 Parity Mode

The SSC allows parity generation for transmission and parity check for reception on frame base. The type of parity can be selected by bit field CCR.PM, common for transmission and reception (no parity, even or odd parity). If the parity handling is disabled, the SSC frame does not contain any parity bit. For consistency reasons, all communication partners have to be programmed to the same parity mode.

Universal Serial Interface Channel (USIC)

If parity generation has been enabled, the transmitter automatically extends the clock by one cycle after the last data word of the data frame, and sends out its calculated parity bit in this cycle.

Figure 14-42 shows how a parity bit is added to the transmitted data bits of a frame. The number of the transmitted bits of a complete frame with parity is always one more than that without parity. The parity bit is transmitted as the last bit of a frame, following the data bits, independent of the shift direction (SCTR.SDIR).

Note: For dual and quad SSC protocols, the parity bit will be transmitted and received only on DOUT0 and DX0 respectively in the extended clock cycle.

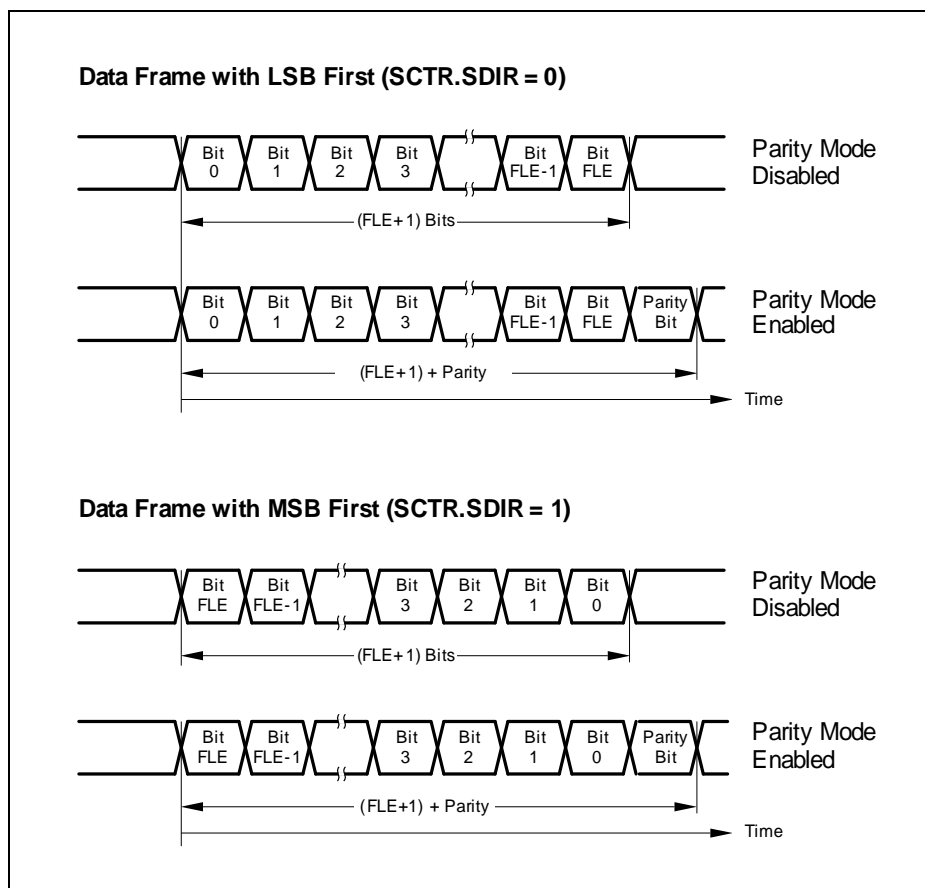

Figure 14-42 Data Frames without/with Parity

Universal Serial Interface Channel (USIC)

Similarly, after the receiver receives the last word of a data frame as defined by FLE, it expects an additional one clock cycle, which will contain the parity bit. The receiver interprets this bit as received parity and separates it from the received data. The received parity bit value is instead monitored in the protocol-related argument (PAR) of the receiver buffer status registers as receiver buffer status information. The receiver compares the bit to its internally calculated parity and the result of the parity check is indicated by the flag PSR.PARERR. The parity error event generates a protocol interrupt if PCR.PARIEN = 1.

Parity bit generation and detection is not supported for the following cases:

- When frame length is 64 data bits or greater, i.e. $FLE = 63_H$;
- When in slave mode, the end of frame occurs before the number of data bits defined by FLE is reached.

14.4.2.6 Transfer Mode

In SSC mode, bit field SCTR.TRM = 01_B has to be programmed to allow data transfers. Setting SCTR.TRM = 00_B disables and stops the data transfer immediately.

14.4.2.7 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to SSC frame handling.

- Transmit buffer interrupt TBI:
Bit PSR.TBIF is set after the start of first data bit of a data word.
- Transmit shift interrupt TSI:
Bit PSR.TSIF is set after the start of the last data bit of a data word.
- Receiver start interrupt RSI:
Bit PSR.RSIF is set after the reception of the first data bit of a data word.
With this event, bit TCSR.TDV is cleared and new data can be loaded to the transmit buffer.
- Receiver interrupt RI:
The reception of the second, third, and all subsequent words in a multi-word frame is always indicated by RBUFSR.SOF = 0. Bit PSR.RIF is set after the reception of the last data bit of a data word if RBUFSR.SOF = 0.
Bit RBUFSR.SOF indicates whether the received data word has been the first data word of a multi-word frame or some subsequent word. In SSC mode, it decides if alternative interrupt or receive interrupt is generated.
- Alternative interrupt AI:
The reception of the first word in a frame is always indicated by RBUFSR.SOF = 1. This is true both in case of reception of multi-word frames and single-word frames. In SSC mode, this results in setting PSR.AIF.

14.4.2.8 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

14.4.2.9 Protocol-Related Argument and Error

The protocol-related argument (RBUFSR.PAR) and the protocol-related error (RBUFSR.PERR) are two flags that are assigned to each received data word in the corresponding receiver buffer status registers.

In SSC mode, the received parity bit is monitored by the protocol-related argument. The received start of frame indication is monitored by the protocol-related error indication (0 = received word is not the first word of a frame, 1 = received word is the first word of a new frame).

Note: For SSC, the parity error event indication bit is located in the PSR register.

14.4.2.10 Receive Buffer Handling

If a receive FIFO buffer is available (CCFG.RB = 1) and enabled for data handling (RBCTR.SIZE > 0), it is recommended to set RBCTR.RCIM = 01_B in SSC mode. This leads to an indication that the data word has been the first data word of a new data frame if bit OUTR.RCI[4] = 1, and the word length of the received data is given by OUTR.RCI[3:0].

The standard receive buffer event and the alternative receive buffer event can be used for the following operation in RCI mode (RBCTR.RNM = 1):

- A standard receive buffer event indicates that a data word can be read from OUTR that has not been the first word of a data frame.
- An alternative receive buffer event indicates that the first data word of a new data frame can be read from OUTR.

14.4.2.11 Multi-IO SSC Protocols

The SSC implements the following three features to support multiple data input/output SSC protocols, such as the dual- and quad-SSC:

1. Data Shift Mode ([Section 14.2.5.2](#))
Configures the data for transmission and reception using one, two or four data lines in parallel, through the bit field SCTR.DSM.
2. Hardware Port Control ([Section 14.2.7](#))
Sets up a dedicated hardware interface to control the direction of the pins overlaid with both DINx and DOUTx functions, through the bit SCTR.HPCDIR.
3. Transmit Control Information ([Section 14.2.5.3](#))
Allows the dynamic control of both the shift mode and pin direction during data transfers by writing to SCTR.DSM and SCTR.HPCDIR with TCI.

Universal Serial Interface Channel (USIC)

Figure 14-43 shows an example of a Quad-SSC protocol, which requires the master SSC to first transmit a command byte (to request a quad output read from the slave) and a dummy byte through a single data line. At the end of the dummy byte, both master and slave SSC switches to quad data lines, and with the roles of transmitter and receiver reversed. The master SSC then receives the data four bits per shift clock from the slave through the MRST[3:0] lines.

Figure 14-43 Quad-SSC Example

To work with the quad-SSC protocol in the given example, the following issues have to be additionally considered on top of those defined in [Section 14.4.3](#) and [Section 14.4.4](#):

- During the initialization phase:
 - Set CCR.HPCEN to 11_B to enable the dedicated hardware interface to the DX0/DOUT0, DX3/DOUT1, DX4/DOUT2 and DX5/DOUT3 pins.
 - Set TCSR.[4:0] to 10_H to enable hardware port control in TC1
- To start the data transfer:
 - For the master SSC, write the command and dummy bytes into TBUF04 to select a single data line in output mode and initiate the data transfer.
 - For the slave SSC, dummy data can be preloaded into TBUF00 to select a single data line in input mode.
- To switch to quad data lines and pin direction:

Universal Serial Interface Channel (USIC)

- For the master SSC, write subsequent dummy data to TBUF03 to select quad data lines in input mode to read in valid slave data.
- For the slave SSC, write valid data to TBUF07 for transmission through quad data lines in output mode.

Note: If DOUT[1:0] or DOUT[3:0] pins are already enabled with CCR.HPCEN but SCTR.DSM does not use all pins, the unused DOUTx pins output the passive data level defined by SCTR.PDL.

Figure 14-44 shows the connections for the Quad-SSC example.

Figure 14-44 Connections for Quad-SSC Example

14.4.3 Operating the SSC in Master Mode

In order to operate the SSC in master mode, the following issues have to be considered:

- **Select SSC mode:**
It is recommended to configure all parameters of the SSC that do not change during run time while CCR.MODE = 0000_B. Bit field SCTR.TRM = 01_B has to be programmed. The configuration of the input stages has to be done while

Universal Serial Interface Channel (USIC)

CCR.MODE = 0000_B to avoid unintended edges of the input signals and the SSC mode can be enabled by CCR.MODE = 0001_B afterwards.

- Pin connections:
Establish a connection of the input stage (DX0, DX3, DX4, DX5) with the selected receive data input pin (DIN[3:0]) with DXnCR.INSW = 1 and configure the transmit data output pin (DOUT[3:0]). One, two or four such connections may be needed depending on the protocol. For half-duplex configurations, hardware port control can be also used to establish the required connections.
- Baud rate generation:
The desired baud rate setting has to be selected, comprising the fractional divider and the baud rate generator. Bit DX1CR.INSW = 0 has to be programmed to use the baud rate generator output SCLK directly as input for the data shift unit. Configure a shift clock output pin (signal SCLKOUT).
- Slave select generation:
The slave select delay generation has to be enabled by setting PCR.MSLSEN = 1 and the programming of the time quanta counter setting. Bit DX2CR.INSW = 0 has to be programmed to use the slave select generator output MSLS as input for the data shift unit. Configure slave select output pins (signals SELOx) if needed.
- Data format configuration:
The word length, the frame length, the shift direction and shift mode have to be set up according to the application requirements by programming the register SCTR.

Note: The USIC can only receive in master mode if it is transmitting, because the master frame handling refers to bit TDV of the transmitter part.

Note: The step to enable the alternate output port functions should only be done after the SSC mode is enabled, to avoid unintended spikes on the output.

14.4.3.1 Baud Rate Generation

The baud rate (determining the length of one data bit) of the SSC is defined by the frequency of the SCLK signal (one period of f_{SCLK} represents one data bit). The SSC baud rate generation does not imply any time quanta counter.

In a standard SSC application, the phase relation between the optional MCLK output signal and SCLK is not relevant and can be disabled (BRG.PPPEN = 0). In this case, the SCLK signal directly derives from the protocol input frequency f_{PIN} . In the exceptional case that a fixed phase relation between the MCLK signal and SCLK is required (e.g. when using MCLK as clock reference for external devices), the additional divider by 2 stage has to be taken into account (BRG.PPPEN = 1).

Universal Serial Interface Channel (USIC)

The adjustable divider factor is defined by bit field BRG.PDIV.

$$f_{\text{SCLK}} = \frac{f_{\text{PIN}}}{2} \times \frac{1}{\text{PDIV} + 1} \quad \text{if } \text{PPPEN} = 0$$

$$f_{\text{SCLK}} = \frac{f_{\text{PIN}}}{2 \times 2} \times \frac{1}{\text{PDIV} + 1} \quad \text{if } \text{PPPEN} = 1$$
(14.8)

14.4.3.2 MSLS Generation

The slave select signals indicate the start and the end of a data frame and are also used by the communication master to individually select the desired slave device. A slave select output of the communication master becomes active a programmable time before a data part of the frame is started (leading delay T_{id}), necessary to prepare the slave device for the following communication. After the transfer of a data part of the frame, it becomes inactive again a programmable time after the end of the last bit (trailing delay T_{id}) to respect the slave hold time requirements. If data frames are transferred back-to-back one after the other, the minimum time between the deactivation of the slave select and the next activation of a slave select is programmable (next-frame delay T_{nf}). If a data frame consists of more than one data word, an optional delay between the data words can also be programmed (inter-word delay T_{iw}).

Figure 14-45 MSLS Generation in SSC Master Mode

In SSC master mode, the slave select delays are defined as follows:

Universal Serial Interface Channel (USIC)

- **Leading delay T_{ld} :**
The leading delay starts if valid data is available for transmission. The internal signal MSLS becomes active with the start of the leading delay. The first shift clock edge (rising edge) of SCLK is generated by the baud rate generator after the leading delay has elapsed.
- **Trailing delay T_{td}**
The trailing delay starts at the end of the last SCLK cycle of a data frame. The internal signal MSLS becomes inactive with the end of the trailing delay.
- **Inter-word delay T_{iw} :**
This delay is optional and can be enabled/disabled by PCR.TIWEN. If the inter-word delay is disabled ($TIWEN = 0$), the last data bit of a data word is directly followed by the first data bit of the next data word of the same data frame. If enabled ($TIWEN = 1$), the inter-word delay starts at the end of the last SCLK cycle of a data word. The first SCLK cycle of the following data word of the same data frame is started when the inter-word delay has elapsed. During this time, no shift clock pulses are generated and signal MSLS stays active. The communication partner has time to “digest” the previous data word or to prepare for the next one.
- **Next-frame delay T_{nf} :**
The next-frame delay starts at the end of the trailing delay. During this time, no shift clock pulses are generated and signal MSLS stays inactive. A frame is considered as finished after the next-frame delay has elapsed.

14.4.3.3 Automatic Slave Select Update

If the number of bits per SSC frame and the word length are defined by bit fields SCTR.FLE and SCTR.WLE, the transmit control information TCI can be used to update the slave select setting PCR.CTR[23:16] to control the SELOx select outputs. The automatic update mechanism is enabled by TCSR.SELMD = 1 (bits TCSR.WLEMD, FLEMD, and WAMD have to be cleared). In this case, the TCI of the first data word of a frame defines the slave select setting of the complete frame due to the automatic shadow mechanism (see [Page 14-62](#)).

14.4.3.4 Slave Select Delay Generation

The slave select delay generation is based on time quanta. The length of a time quantum (defined by the period of the f_{CTQIN}) and the number of time quanta per delay can be programmed.

In standard SSC applications, the leading delay T_{ld} and the trailing delay T_{td} are mainly used to ensure stability on the input and output lines as well as to respect setup and hold times of the input stages. These two delays have the same length (in most cases shorter than a bit time) and can be programmed with the same set of bit fields.

- **BRG.CTQSEL**
to define the input frequency f_{CTQIN} for the time quanta generation for T_{ld} and T_{td}
- **BRG.PCTQ**
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4) for T_{ld} and T_{td}
- **BRG.DCTQ**
to define the number of time quanta for the delay generation for T_{ld} and T_{td}

The inter-word delay T_{iw} and the next-frame delay T_{nf} are used to handle received data or to prepare data for the next word or frame. These two delays have the same length (in most cases in the bit time range) and can be programmed with a second, independent set of bit fields.

- **PCR.CTQSEL1**
to define the input frequency f_{CTQIN} for the time quanta generation for T_{nf} and T_{iw}
- **PCR.PCTQ1**
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4) for T_{nf} and T_{iw}
- **PCR.DCTQ1**
to define the number of time quanta for the delay generation for T_{nf} and T_{iw}
- **PCR.TIWEN**
to enable/disable the inter-word delay T_{iw}

Each delay depends on the length of a time quantum and the programmed number of time quanta given by the bit fields CTQSEL/CTQSEL1, PCTQ/DCTQ and PCTQ1/DCTQ1 (the coding of CTQSEL1 is similar to CTQSEL, etc.). To provide a high flexibility in programming the delay length, the input frequencies can be selected between several possibilities (e.g. based on bit times or on the faster inputs of the protocol-related divider). The delay times are defined as follows:

$$T_{ld} = T_{td} = \frac{(PCTQ + 1) \times (DCTQ + 1)}{f_{CTQIN}} \quad (14.9)$$

$$T_{iw} = T_{nf} = \frac{(PCTQ1 + 1) \times (DCTQ1 + 1)}{f_{CTQIN}}$$

14.4.3.5 Protocol Interrupt Events

The following protocol-related events generated in SSC mode and can lead to a protocol interrupt. They are related to the start and the end of a data frame. After the start of a data frame a new setting could be programmed for the next data frame and after the end of a data frame the SSC connections to pins can be changed.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- **MSLS Interrupt:**
This interrupt indicates in master mode (MSLS generation enabled) that a data frame has started (activation of MSLS) and has been finished (deactivation of MSLS). Any change of the internal MSLS signal sets bit PSR.MSLSEV and additionally, a protocol interrupt can be generated if PCR.MSLSIEN = 1. The actual state of the internal MSLS signal can be read out at PSR.MSLS to take appropriate actions when this interrupt has been detected.
- **DX2T Interrupt:**
This interrupt monitors edges of the input signal of the DX2 stage (although this signal is not used as slave select input for data transfers).
A programmable edge detection for the DX2 input signal sets bit PSR.DX2TEV and additionally, a protocol interrupt can be generated if PCR.DX2TIEN = 1. The actual state of the selected input signal can be read out at PSR.DX2S to take appropriate actions when this interrupt has been detected.
- **Parity Error Interrupt:**
This interrupt indicates that there is a mismatch in the received parity bit (in RBUFSR.PAR) with the calculated parity bit of the last received word of a data frame.

14.4.3.6 End-of-Frame Control

The information about the frame length is required for the MSLS generator of the master device. In addition to the mechanism based on the number of bits per frame (selected with $SCTR.FLE < 63$), the following alternative mechanisms for end of frame handling are supported. It is recommended to set $SCTR.FLE = 63$ (if several end of frame mechanisms are activated in parallel, the first end condition being found finishes the frame).

- **Software-based start of frame indication TCSR.SOF:**
 This mechanism can be used if software handles the TBUF data without data FIFO. If bit SOF is set, a valid content of TBUF is considered as first word of a new frame. Bit SOF has to be set before the content of TBUF is transferred to the transmit shift register, so it is recommended to write it before writing data to TBUF. A current data word transfer is finished completely and the slave select delays T_{td} and T_{nf} are applied before starting a new data frame with T_{td} and the content of TBUF. For software-handling of bit SOF, bit TCSR.WLEMD = 0 has to be programmed. In this case, all TBUF[31:0] address locations show an identical behavior (TCI not taken into account for data handling).
- **Software-based end of frame indication TCSR.EOF:**
 This mechanism can be used if software handles the TBUF data without data FIFO. If bit EOF is set, a valid content of TBUF is considered as last word of a new frame. Bit EOF has to be set before the content of TBUF is transferred to the transmit shift register, so it is recommended to write it before writing data to TBUF. The data word in TBUF is sent out completely and the slave select delays T_{td} and T_{nf} are applied. A new data frame can start with T_{td} with the next valid TBUF value. For software-handling of bit EOF, bit TCSR.WLEMD = 0 has to be programmed. In this case, all TBUF[31:0] address locations show an identical behavior (TCI not taken into account for data handling).
- **Software-based address related end of frame handling:**
 This mechanism can be used if software handles the TBUF data without data FIFO. If bit TCSR.WLEMD = 1, the address of the written TBUF[31:0] is used as transmit control information TCI[4:0] to update $SCTR.WLE (= TCI[3:0])$ and TCSR.EOF (= TCI[4]) for each data word. The written TBUF[31:0] address location defines the word length and the end of a frame (locations TBUF[31:16] lead to a frame end). For example, writing transmit data to TBUF[07] results in a data word of 8-bit length without finishing the frame, whereas writing transmit data to TBUF[31] leads to a data word length of 16 bits, followed by T_{td} , the deactivation of MSLS and T_{nf} . If TCSR.WLEMD = 1, bits TCSR.EOF and SOF, as well as SCTR.WLE must not be written by software after writing data to a TBUF location. Furthermore, it is recommended to clear bits TCSR.SELMD, FLEMD and WAMD.
- **FIFO-based address related end of frame handling:**
 This mechanism can be used if a data FIFO is used to store the transmit data. The general behavior is similar to the software-based address related end of frame

Universal Serial Interface Channel (USIC)

handling, except that transmit data is not written to the locations TBUF[31:0], but to the FIFO input locations IN[31:0] instead. In this case, software must not write to any of the TBUF locations.

- TBUF related end of frame handling:
If bit PCR.FEM = 0, an end of frame is assumed if the transmit buffer TBUF does not contain valid transmit data at the end of a data word transmission (TCSR.TDV = 0 or in Stop Mode). In this case, the software has to take care that TBUF does not run empty during a data frame in Run Mode. If bit PCR.FEM = 1, signal MSLS stays active while the transmit buffer is waiting for new data (TCSR.TDV = 1 again) or until Stop Mode is left.
- Explicit end of frame by software:
The software can explicitly stop a frame by clearing bit PSR.MSLS by writing a 1 to the related bit position in register PSCR. This write action immediately clears bit PSR.MSLS, whereas the internal MSLS signal becomes inactive after finishing a currently running word transfer and respecting the slave select delays T_{id} and T_{nf} .

14.4.4 Operating the SSC in Slave Mode

In order to operate the SSC in slave mode, the following issues have to be considered:

- **Select SSC mode:**
It is recommended to configure all parameters of the SSC that do not change during run time while $CCR.MODE = 0000_B$. Bit field $SCTR.TRM = 01_B$ has to be programmed. The configuration of the input stages has to be done while $CCR.MODE = 0000_B$ to avoid unintended edges of the input signals and the SSC mode can be enabled afterwards by $CCR.MODE = 0001_B$.
- **Pin connections:**
Establish the connection of the input stage (DX0, DX3, DX4, DX5) with the selected receive data input pin ($DIN[3:0]$) with $DXnCR.INSW = 1$ and configure the transmit data output pin ($DOUT[3:0]$). One, two or four such connections may be needed depending on the protocol. For half-duplex configurations, hardware port control can be also used to establish the required connections.
Establish a connection of input stage DX1 with the selected shift clock input pin (signal SCLKIN) with $DX1CR.INSW = 1$.
Establish a connection of input stage DX2 with the selected slave select input pin (signal SELIN) with $DX2CR.INSW = 1$. If no slave select input signal is used, the DX2 stage has to deliver a 1-level to the data shift unit to allow data reception and transmission. If a slave device is not selected (DX2 stage delivers a 0 to the data shift unit) and a shift clock pulse are received, the incoming data is not received and the $DOUTx$ signal outputs the passive data level defined by $SCTR.PDL$.
Note that the step to enable the alternate output port functions should only be done after the SSC mode is enabled, to avoid unintended spikes on the output.
- **Baud rate generation:**
The baud rate generator is not needed and can be switched off by the fractional divider.
- **Data format configuration:**
If required, the shift mode can be set up for reception and/or transmission of two or four data bits at one time by programming the register $SCTR$.
- **Slave select generation:**
The slave select delay generation is not needed and can be switched off. The bits and bit fields $MSLSEN$, $SELCTR$, $SELINV$, $CTQSEL1$, $PCTQ1$, $DCTQ1$, $MSLSIEN$, $SELO[7:0]$, and $TIWEN$ in register PCR are not necessary and can be programmed to 0.

14.4.4.1 Protocol Interrupts

The following protocol-related events generated in SSC mode and can lead to a protocol interrupt. They are related to the start and the end of a data frame. After the start of a data frame a new setting could be programmed for the next data frame and after the end of a data frame the SSC connections to pins can be changed.

Universal Serial Interface Channel (USIC)

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- **MSLS event:**
The MSLS generation being switched off, this event is not available.
- **DX2T event:**
The slave select input signal SELIN is handled by the DX2 stage and the edges of the selected signal can generate a protocol interrupt. This interrupt allows to indicate that a data frame has started and/or that a data frame has been completely finished. A programmable edge detection for the DX2 input signal activates DX2T, sets bit PSR.DX2TEV and additionally, a protocol interrupt can be generated if PCR.DX2TIEN = 1. The actual state of the selected input signal can be read out at PSR.DX2S to take appropriate actions when this interrupt has been detected.
- **Parity Error Interrupt:**
This interrupt indicates that there is a mismatch in the received parity bit (in RBUFSR.PAR) with the calculated parity bit of the last received word of a data frame.

14.4.4.2 End-of-Frame Control

In slave mode, the following possibilities exist to determine the frame length. The slave device either has to refer to an external slave select signal, or to the number of received data bits.

- **Frame length known in advance by the slave device, no slave select:**
In this case bit field SCTR.FLE can be programmed to the known value (if it does not exceed 63 bits). A currently running data word transfer is considered as finished if the programmed frame length is reached.
- **Frame length not known by the slave, no slave select:**
In this case, the slave device's software has to decide on data word base if a frame is finished. Bit field SCTR.FLE can be either programmed to the word length SCTR.WLE, or to its maximum value to disable the slave internal frame length evaluation by counting received bits.
- **Slave device addressed via slave select signal SELIN:**
If the slave device is addressed by a slave select signal delivered by the communication master, the frame start and end information are given by this signal. In this case, bit field SCTR.FLE should be programmed to its maximum value to disable the slave internal frame length evaluation.

Universal Serial Interface Channel (USIC)

14.4.5 SSC Protocol Registers

In SSC mode, the registers PCR and PSR handle SSC related information.

14.4.5.1 SSC Protocol Control Registers

In SSC mode, the PCR register bits or bit fields are defined as described in this section.

PCR

Protocol Control Register [SSC Mode]

(3C_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |

| rw | rw | rw | rw | | | | rw | | rw | | rw | rw | rw | rw | |

| Field | Bits | Type | Description |
|--------|------|------|---|
| MSLSEN | 0 | rw | MSLS Enable This bit enables/disables the generation of the master slave select signal MSLS. If the SSC is a transfer slave, the SLS information is read from a pin and the internal generation is not needed. If the SSC is a transfer master, it has to provide the MSLS signal. 0 _B The MSLS generation is disabled (MSLS = 0). This is the setting for SSC slave mode. 1 _B The MSLS generation is enabled. This is the setting for SSC master mode. |
| SELCTR | 1 | rw | Select Control This bit selects the operating mode for the SELO[7:0] outputs. 0 _B The coded select mode is enabled. 1 _B The direct select mode is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| SELINV | 2 | rw | Select Inversion This bit defines if the polarity of the SELO[7:0] outputs in relation to the master slave select signal MSLS. 0_B The SELO outputs have the same polarity as the MSLS signal (active high). 1_B The SELO outputs have the inverted polarity to the MSLS signal (active low). |
| FEM | 3 | rw | Frame End Mode This bit defines if a transmit buffer content that is not valid for transmission is considered as an end of frame condition for the slave select generation. 0_B The current data frame is considered as finished when the last bit of a data word has been sent out and the transmit buffer TBUF does not contain new data ($TDV = 0$). 1_B The MSLS signal is kept active also while no new data is available and no other end of frame condition is reached. In this case, the software can accept delays in delivering the data without automatic deactivation of MSLS in multi-word data frames. |
| CTQSEL1 | [5:4] | rw | Input Frequency Selection This bit field defines the input frequency f_{CTQIN} for the generation of the slave select delays T_{iw} and T_{nf} . 00_B $f_{CTQIN} = f_{PDIV}$ 01_B $f_{CTQIN} = f_{PPP}$ 10_B $f_{CTQIN} = f_{SCLK}$ 11_B $f_{CTQIN} = f_{MCLK}$ |
| PCTQ1 | [7:6] | rw | Divider Factor PCTQ1 for T_{iw} and T_{nf} This bit field represents the divider factor PCTQ1 (range = 0 - 3) for the generation of the inter-word delay and the next-frame delay. $T_{iw} = T_{nf} = 1/f_{CTQIN} \times (PCTQ1 + 1) \times (DCTQ1 + 1)$ |
| DCTQ1 | [12:8] | rw | Divider Factor DCTQ1 for T_{iw} and T_{nf} This bit field represents the divider factor DCTQ1 (range = 0 - 31) for the generation of the inter-word delay and the next-frame delay. $T_{iw} = T_{nf} = 1/f_{CTQIN} \times (PCTQ1 + 1) \times (DCTQ1 + 1)$ |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| PARIEN | 13 | rw | Parity Error Interrupt Enable This bit enables/disables the generation of a protocol interrupt with the detection of a parity error. 0 _B A protocol interrupt is not generated with the detection of a parity error. 1 _B A protocol interrupt is generated with the detection of a parity error. |
| MSLSIEN | 14 | rw | MSLS Interrupt Enable This bit enables/disables the generation of a protocol interrupt if the state of the MSLS signal changes (indicated by PSR.MSLSEV = 1). 0 _B A protocol interrupt is not generated if a change of signal MSLS is detected. 1 _B A protocol interrupt is generated if a change of signal MSLS is detected. |
| DX2TIEN | 15 | rw | DX2T Interrupt Enable This bit enables/disables the generation of a protocol interrupt if the DX2T signal becomes activated (indicated by PSR.DX2TEV = 1). 0 _B A protocol interrupt is not generated if DX2T is activated. 1 _B A protocol interrupt is generated if DX2T is activated. |
| SELO | [23:16] | rw | Select Output This bit field defines the setting of the SELO[7:0] output lines. 0 _B The corresponding SELOx line cannot be activated. 1 _B The corresponding SELOx line can be activated (according to the mode selected by SELCTR). |
| TIWEN | 24 | rw | Enable Inter-Word Delay T_{iw} This bit enables/disables the inter-word delay T _{iw} after the transmission of a data word. 0 _B No delay between data words of the same frame. 1 _B The inter-word delay T _{iw} is enabled and introduced between data words of the same frame. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| SLPHSEL | 25 | rw | Slave Mode Clock Phase Select This bit selects the clock phase for the data shifting in slave mode. 0_B Data bits are shifted out with the leading edge of the shift clock signal and latched in with the trailing edge. 1_B The first data bit is shifted out when the data shift unit receives a low to high transition from the DX2 stage. Subsequent bits are shifted out with the trailing edge of the shift clock signal. Data bits are always latched in with the leading edge. |
| MCLK | 31 | rw | Master Clock Enable This bit enables/disables the generation of the master clock output signal MCLK, independent from master or slave mode. 0_B The MCLK generation is disabled and output MCLK = 0. 1_B The MCLK generation is enabled. |
| 0 | [30:26] | rw | Reserved Returns 0 if read; should be written with 0. |

Universal Serial Interface Channel (USIC)

14.4.5.2 SSC Protocol Status Register

In SSC mode, the PSR register bits or bit fields are defined as described in this section. The bits and bit fields in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. The PSR flags should be cleared by software before enabling a new protocol.

PSR

Protocol Status Register [SSC Mode] (48_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |

| TBIF | 13 | rwh | Transmit Buffer Indication Flag 0 _B A transmit buffer event has not occurred. 1 _B A transmit buffer event has occurred. |
| RIF | 14 | rwh | Receive Indication Flag 0 _B A receive event has not occurred. 1 _B A receive event has occurred. |
| AIF | 15 | rwh | Alternative Receive Indication Flag 0 _B An alternative receive event has not occurred. 1 _B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0 _B A baud rate generator event has not occurred. 1 _B A baud rate generator event has occurred. |
| 0 | [9:5], [31:17] | r | Reserved Returns 0 if read; not modified in SSC mode. |

1) This status bit can generate a protocol interrupt in SSC mode (see [Page 14-22](#)). The general interrupt status flags are described in the general interrupt chapter.

14.4.6 SSC Timing Considerations

The input and output signals have to respect certain timings in order to ensure correct data reception and transmission. In addition to module internal timings (due to input filters, reaction times on events, etc.), also the timings from the input pin via the input stage (T_{in}) to the module and from the module via the output driver stage to the pin (T_{out}), as well as the signal propagation on the wires (T_{prop}) have to be taken into account.

Please note that there might be additional delays in the DXn input stages, because the digital filter and the synchronization stages lead to systematic delays, that have to be considered if these functions are used.

14.4.6.1 Closed-loop Delay

A system-inherent limiting factor for the baud rate of an SSC connection is the closed-loop delay. In a typical application setup, a communication master device is connected to a slave device in full-duplex mode with independent lines for transmit and receive data. In a general case, all transmitters refer to one shift clock edge for transmission and all receivers refer to the other shift clock edge for reception. The master device's SSC module sends out the transmit data, the shift clock and optionally the slave select signal. Therefore, the baud rate generation (BRG) and slave select generation (SSG) are part of the master device. The frame control is similar for SSC modules in master and slave mode, the main difference is the fact which module generates the shift clock and optionally, the slave select signals.

Figure 14-46 SSC Closed-loop Delay

Universal Serial Interface Channel (USIC)

The signal path between the SSC modules of the master and the slave device includes the master's output driver, the wiring to the slave device and the slave device's input stage. With the received shift clock edges, the slave device receives the master's transmit data and transmits its own data back to the master device, passing by a similar signal path in the other direction. The master module receives the slave's transmit data related to its internal shift clock edges. In order to ensure correct data reception in the master device, the slave's transmit data has to be stable (respecting setup and hold times) as master receive data with the next shift clock edge of the master (generally 1/2 shift clock period). To avoid data corruption, the accumulated delays of the input and output stages, the signal propagation on the wiring and the reaction times of the transmitter/receiver have to be carefully considered, especially at high baud rates.

In the given example, the time between the generation of the shift clock signal and the evaluation of the receive data by the master SSC module is given by the sum of $T_{\text{out_master}} + 2 \times T_{\text{prop}} + T_{\text{in_slave}} + T_{\text{out_slave}} + T_{\text{in_master}}$ + module reaction times + input setup times.

The input path is characterized by an input delay depending mainly on the input stage characteristics of the pads. The output path delay is determined by the output driver delay and its slew rate, the external load and current capability of the driver. The device specific values for the input/output driver are given in the Data Sheet.

Universal Serial Interface Channel (USIC)

Figure 14-47 describes graphically the closed-loop delay and the effect of two delay compensation options discussed in [Section 14.4.6.2](#) and [Section 14.4.6.3](#).

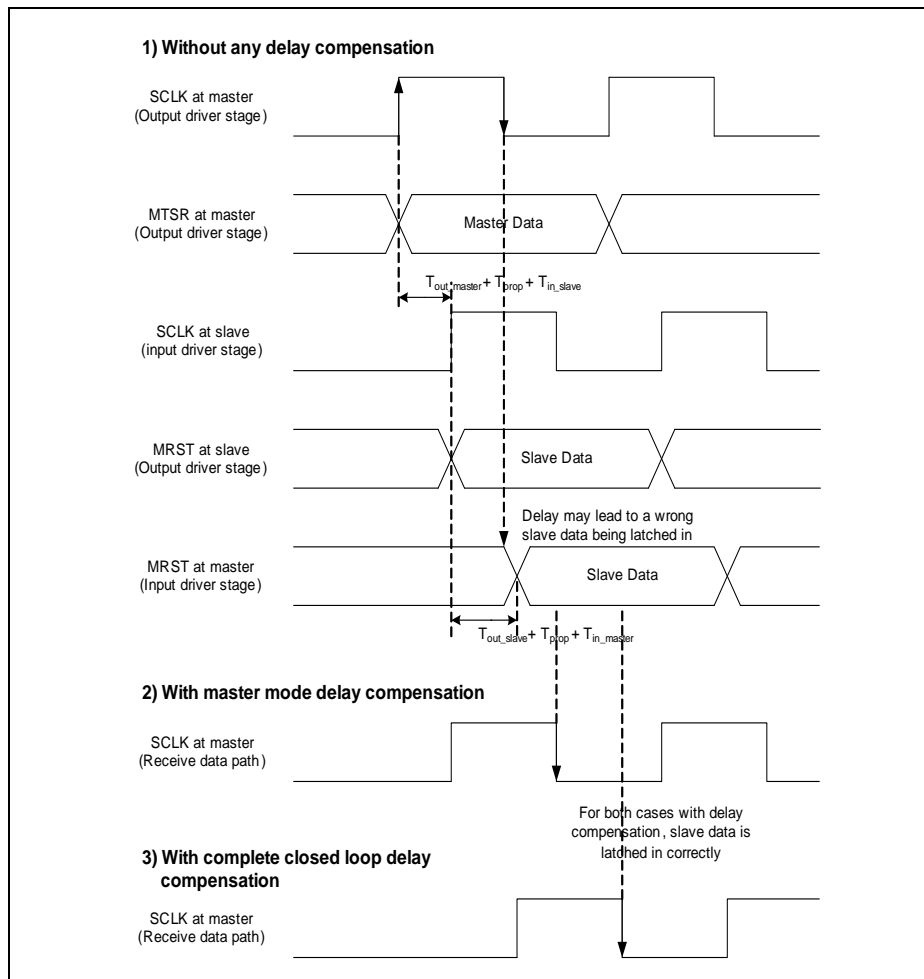

Figure 14-47 SSC Closed-loop Delay Timing Waveform

Universal Serial Interface Channel (USIC)

14.4.6.2 Delay Compensation in Master Mode

A higher baud rate can be reached by delay compensation in master mode. This compensation is possible if (at least) the shift clock pin is bidirectional.

Figure 14-48 SSC Master Mode with Delay Compensation

If the receive shift clock signal in master mode is directly taken from the input function in parallel to the output signal, the output delay of the master device's shift clock output is compensated and only the difference between the input delays of the master and the slave devices have to be taken into account instead of the complete master's output delay and the slave's input delay of the shift clock path. The delay compensation is enabled with $DX1CR.DCEN = 1$ while $DX1CR.INSW = 0$ (transmit shift clock is taken from the baud-rate generator).

In the given example, the time between the evaluation of the shift clock signal and the receive data by the master SSC module is reduced by $T_{in_master} + T_{out_master}$.

Although being a master mode, the shift clock input and optionally the slave select signal are not directly connected internally to the data shift unit, but are taken as external signals from input pins. The delay compensation does not lead to additional pins for the SSC communication if the shift clock output pin (slave select output pin, respectively) is/are bidirectional. In this case, the input signal is decoupled from other internal signals, because it is related to the signal level at the pin itself.

14.4.6.3 Complete Closed-loop Delay Compensation

Alternatively, the complete closed-loop delay can be compensated by using one additional pin on both the SSC master and slave devices for the SSC communication.

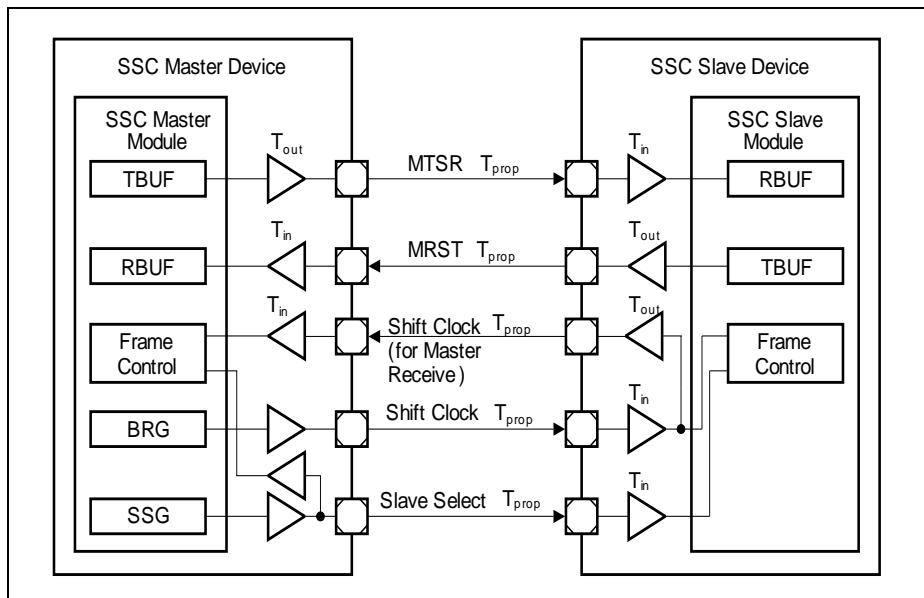

Figure 14-49 SSC Complete Closed-loop Delay Compensation

The principle behind this delay compensation method is to have the slave feedback the shift clock back to the master, which uses it as the receive shift clock. By going through a complete closed-loop signal path, the receive shift clock is thus fully compensated.

The slave has to setup the SCLKOUT pin function to output the shift clock by setting the bit BRG.SCLKOSEL to 1, while the master has to setup the DX1 pin function to receive the shift clock from the slave and enable the delay compensation with DX1CR.DCEN = 1 and DX1CR.INSW = 0.

14.5 Inter-IC Bus Protocol (IIC)

The IIC protocol of the USIC refers to the IIC bus specification [7]. Contrary to that specification, the USIC device assumes rise/fall times of the bus signals of max. 300 ns in all modes. Please refer to the pad characteristics in the AC/DC chapter for the driver capability. CBUS mode and HS mode are not supported.

The IIC mode is selected by $CCR.MODE = 0100_B$ with $CCFG.IIC = 1$ (IIC mode available).

14.5.1 Introduction

USIC IIC Features:

- Two-wire interface, with one line for shift clock transfer and synchronization (shift clock SCL), the other one for the data transfer (shift data SDA)
- Communication in standard mode (100 kBit/s) or in fast mode (up to 400 kBit/s)
- Support of 7-bit addressing, as well as 10-bit addressing
- Master mode operation, where the IIC controls the bus transactions and provides the clock signal.
- Slave mode operation, where an external master controls the bus transactions and provides the clock signal.
- Multi-master mode operation, where several masters can be connected to the bus and bus arbitration can take place, i.e. the IIC module can be master or slave. The master/slave operation of an IIC bus participant can change from frame to frame.
- Efficient frame handling (low software effort)
- Powerful interrupt handling due to multitude of indication flags
- Compensation support for input delays

14.5.1.1 Signal Description

An IIC connection is characterized by two wires (SDA and SCL). The output drivers for these signals must have open-drain characteristics to allow the wired-AND connection of all SDA lines together and all SCL lines together to form the IIC bus system. Due to this structure, a high level driven by an output stage does not necessarily lead immediately to a high level at the corresponding input. Therefore, each SDA or SCL connection has to be input and output at the same time, because the input function always monitors the level of the signal, also while sending.

- Shift data SDA: input handled by DX0 stage, output signal DOUT0
- Shift clock SCL: input handled by DX1 stage, output signal SCLKOUT

Figure 14-29 shows a connection of two IIC bus participants (modules IIC A and IIC B) using the USIC. In this example, the pin assignment of module IIC A shows separate pins for the input and output signals for SDA and SCL. This assignment can be used if the application does not provide pins having DOUT0 and a DX0 stage input for the same pin

Universal Serial Interface Channel (USIC)

(similar for SCLKOUT and DX1). The pin assignment of module IIC B shows the connection of DOUT0 and a DX0 input at the same pin, also for SCLKOUT and a DX1 input.

Figure 14-50 IIC Signal Connections

14.5.1.2 Symbols

A symbol is a sequence of edges on the lines SDA and SCL. Symbols contain 10 or 25 time quanta t_q , depending on the selected baud rate. The baud rate generator determines the length of the time quanta t_q , the sequence of edges in a symbol is handled by the IIC protocol pre-processor, and the sequence of symbols can be programmed by the user according to the application needs.

The following symbols are defined:

- Bus idle:
SDA and SCL are high. No data transfer takes place currently.
- Data bit symbol:
SDA stable during the high phase of SCL. SDA then represents the transferred bit value. There is one clock pulse on SCL for each transferred bit of data. During data transfers SDA may only change while SCL is low.

Universal Serial Interface Channel (USIC)

- **Start symbol:**
Signal SDA being high followed by a falling edge of SDA while SCL is high indicates a start condition. This start condition initiates a data transfer over the IIC bus after the bus has been idle.
- **Repeated start symbol:**
This start condition initiates a data transfer over the bus after a data symbol when the bus has not been idle. Therefore, SDA is set high and SCL low, followed by a start symbol.
- **Stop symbol:**
A rising edge on SDA while SCL is high indicates a stop condition. This stop condition terminates a data transfer to release the bus to idle state. Between a start condition and a stop condition an arbitrary number of bytes may be transferred.

14.5.1.3 Frame Format

Data is transferred by the 2-line IIC bus (SDA, SCL) using a protocol that ensures reliable and efficient transfers. The sender of a (data) byte receives and checks the value of the following acknowledge field. The IIC being a wired-AND bus system, a 0 of at least one device leads to a 0 on the bus, which is received by all devices.

A data word consists of 8 data bit symbols for the data value, followed by another data bit symbol for the acknowledge bit. The data word can be interpreted as address information (after a start symbol) or as transferred data (after the address).

In order to be able to receive an acknowledge signal, the sender of the data bits has to release the SDA line by sending a 1 as acknowledge value. Depending on the internal state of the receiver, the acknowledge bit is either sent active or passive.

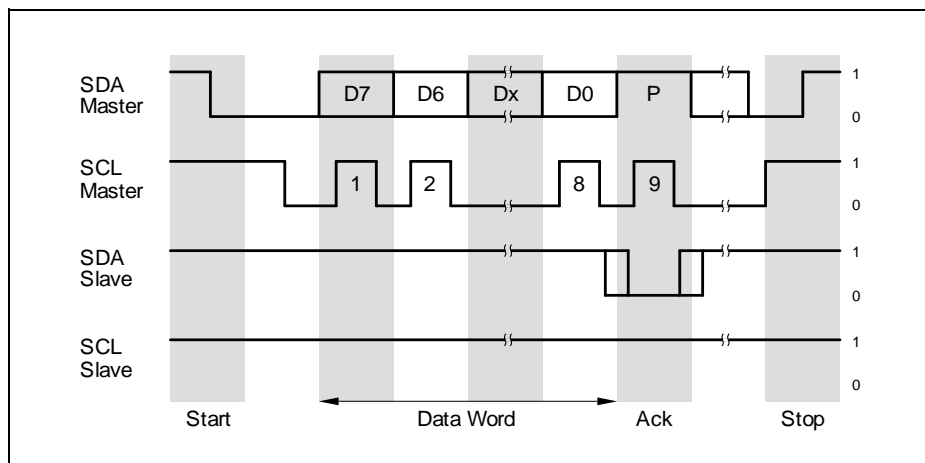

Figure 14-51 IIC Frame Example (simplified)

14.5.2 Operating the IIC

In order to operate the IIC protocol, the following issues have to be considered:

- **Select IIC mode:**
It is recommended to configure all parameters of the IIC that do not change during run time while $CCR.MODE = 0000_B$. Bit field $SCTR.TRM = 11_B$ should be programmed. The configuration of the input stages has to be done while $CCR.MODE = 0000_B$ to avoid unintended edges of the input signals and the IIC mode can be enabled by $CCR.MODE = 0100_B$ afterwards.
- **Pin connections:**
Establish a connection of input stage DX0 (with $DX0CR.DPOL = 0$) to the selected shift data pin SDA (signal DIN0) with $DX0CR.INSW = 0$ and configure the transmit data output signal DOUT0 (with $SCTR.DOCFG = 00_B$) to the same pin. If available, this can be the same pin for input and output, or connect the selected input pin and the output pin to form the SDA line.
The same mechanism applies for the shift clock line SCL. Here, signal SCLKOUT (with $BRG.SCLKCFG = 00_B$) and an input of the DX1 stage have to be connected (with $DX1CR.DPOL = 0$).
The input stage DX2 is not used for the IIC protocol.
If the digital input filters are enabled in the DX0/1 stages, their delays have to be taken into account for correct calculation of the signal timings.
The pins used for SDA and SCL have to be set to open-drain mode to support the wired-AND structure of the IIC bus lines.
Note that the step to enable the alternate output port functions should only be done after the IIC mode is enabled, to avoid unintended spikes on the output.
- **Bit timing configuration:**
In standard mode (100 kBit/s) a minimum module frequency of 2 MHz is necessary, whereas in fast mode (400 kBit/s) a minimum of 10 MHz is required. Additionally, if the digital filter stage should be used to eliminate spikes up to 50 ns, a filter frequency of 20 MHz is necessary.
There could be an uncertainty in the SCL high phase timing of maximum $1/f_{PP}$ if another IIC participant lengthens the SCL low phase on the bus.
More details are given in [Section 14.5.3](#).
- **Data format configuration:**
The data format has to be configured for 8 data bits ($SCTR.WLE = 7$), unlimited data flow ($SCTR.FLE = 3F_H$), and MSB shifted first ($SCTR.SDIR = 1$). The parity generation has to be disabled ($CCR.PM = 00_B$).
- **General hints:**
The IIC slave module becomes active (for reception or transmission) if it is selected by the address sent by the master. In the case that the slave sends data to the master, it uses the transmit path. So a master must not request to read data from the slave address defined for its own channel in order to avoid collisions.
The built-in error detection mechanisms are only activated while the IIC module is

Universal Serial Interface Channel (USIC)

taking part in IIC bus traffic.

If the slave can not deal with too high frequencies, it can lengthen the low phase of the SCL signal.

For data transfers according to the IIC specification, the shift data line SDA shall only change while $SCL = 0$ (defined by IIC bus specification).

14.5.2.1 Transmission Chain

The IIC bus protocol requiring a kind of in-bit-response during the arbitration phase and while a slave is transmitting, the resulting loop delay of the transmission chain can limit the reachable maximal baud rate, strongly depending on the bus characteristics (bus load, module frequency, etc.).

Figure 14-50 shows the general signal path and the delays in the case of a slave transmission. The shift clock SCL is generated by the master device, output on the wire, then it passes through the input stage and the input filter. Now, the edges can be detected and the SDA data signal can be generated accordingly. The SDA signal passes through the output stage and the wire to the master receiver part. There, it passes through the input stage and the input filter before it is sampled.

This complete loop has to be finished (including all settling times to obtain stable signal levels) before the SCL signal changes again. The delays in this path have to be taken into account for the calculation of the baud rate as a function of f_{PERIPH} and f_{PPP} .

14.5.2.2 Byte Stretching

If a device is selected as transceiver and should transmit a data byte but the transmit buffer TBUF does not contain valid data to be transmitted, the device ties down $SCL = 0$ at the end of the previous acknowledge bit. The waiting period is finished if new valid data has been detected in TBUF.

14.5.2.3 Master Arbitration

During the address and data transmission, the master transmitter checks at the rising edge of SCL for each data bit if the value it is sending is equal to the value read on the SDA line. If yes, the next data bit values can be 0. If this is not the case (transmitted value = 1, value read = 0), the master has lost the transmit arbitration. This is indicated by status flag PSR.ARL and can generate a protocol interrupt if enabled by PCR.ARLIEN.

When the transmit arbitration has been lost, the software has to initialize the complete frame again, starting with the first address byte together with the start condition for a new master transmit attempt. Arbitration also takes place for the ACK bit.

14.5.2.4 Non-Acknowledge and Error Conditions

In case of a non-acknowledge or an error, the TCSR.TDV flag remains set, but no further transmission will take place. User software must invalidate the transmit buffer and disable transmissions (by writing FMRL.MTDV = 10_B), before configuring the transmission (by writing TBUF) again with appropriate values to react on the previous event. In the case the FIFO data buffer is used, additionally the FIFO buffer needs to be flushed and filled again.

14.5.2.5 Mode Control Behavior

In multi-master mode, only run mode 0 and stop mode 0 are supported, the other modes must not be programmed.

- **Run Mode 0:**
Behavior as programmed. If TCSR.TDV = 0 (no new valid TBUF entry found) when a new TBUF entry needs to be processed, the IIC module waits for TDV becoming set to continue operation.
- **Run Mode 1:**
Behavior as programmed. If in master mode, TCSR.TDV = 0 (no new valid TBUF entry found) when a new TBUF entry needs to be processed, the IIC module sends a stop condition to finish the frame. In slave mode, no difference to run mode 0.
- **Stop Mode 0:**
Bit TCSR.TDV is internally considered as 0 (the bit itself is not modified by the stop mode). A currently running word is finished normally, but no new word is started in case of master mode (wait for TDV active).
Bit TDV being considered as 0 for master and slave, the slave will force a wait state on the bus if read by an external master, too.
Additionally, it is not possible to force the generation of a STOP condition out of the wait state. The reason is, that a master read transfer must be finished with a not-acknowledged followed by a STOP condition to allow the slave to release his SDA line. Otherwise the slave may force the SDA line to 0 (first data bit of next byte) making it impossible to generate the STOP condition (rising edge on SDA).
To continue operation, the mode must be switched to run mode 0
- **Stop Mode 1:**
Same as stop mode 0, but additionally, a master sends a STOP condition to finish the frame.
If stop mode 1 is requested for a master device after the first byte of a 10 bit address, a stop condition will be sent out. In this case, a slave device will issue an error interrupt.

14.5.2.6 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to IIC frame handling. As the data input and output pins are the same in IIC protocol, a IIC transmitter also receives the

Universal Serial Interface Channel (USIC)

output data at its input pin. However, no receive related interrupts will be generated in this case.

- **Transmit buffer event:**
The transmit buffer event indication flag PSR.TBIF is set when the content of the transmit buffer TBUF has been loaded to the transmit shift register, indicating that the action requested by the TBUF entry has started.
With this event, bit TCSR.TDV is cleared. This interrupt can be used to write the next TBUF entry while the last one is in progress (handled by the transmitter part).
- **Receive event:**
This receive event indication flag PSR.RIF indicates that a new data byte has been written to the receive buffer RBUF0/1 (except for the first data byte of a new frame, that is indicated by an alternative receive interrupt). The flag becomes set when the data byte is received (after the falling edge of SCL). This interrupt can be used to read out the received data while a new data byte can be in progress (handled by the receiver part).
- **Alternate receive event:**
The alternative receive event indication flag AIF is based on bit RBUFSR[9] (same as RBUF[9]), indicating that the received data word has been the first data word of a new data frame.
- **Transmit shift event:**
The transmit shift event indication flag TSIF is set after the start of the last data bit of a data byte.
- **Receive start event:**
The receive start event indication flag RSIF is set after the sample point of the first data bit of a data byte.

Note: The transmit shift and receive start events can be ignored if the application does not require them during the IIC data transfer.

14.5.2.7 IIC Protocol Interrupt Events

The following protocol-related events are generated in IIC mode and can lead to a protocol interrupt.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- start condition received at a correct position in a frame (PSR.SCR)
- repeated start condition received at a correct position in a frame (PSR.RSCR)
- stop condition transferred at a correct position in a frame (PSR.PCR)
- master arbitration lost (PSR.ARL)
- slave read requested (PSR.SRR)
- acknowledge received (PSR.ACK)
- non-acknowledge received (PSR.NACK)
- start condition not at the expected position in a frame (PSR.ERR)

Universal Serial Interface Channel (USIC)

- stop condition not at the expected position in a frame (PSR.ERR)
- as slave, 10-bit address interrupted by a stop condition after the first address byte (PSR.ERR)
- TDF slave code in master mode (PSR.WTDF)
- TDF master code in slave mode (PSR.WTDF)
- Reserved TDF code found (PSR.WDTF)
- Start condition code during a running frame in master mode (PSR.WTDF)
- Data byte transmission code after transfer direction has been changed to reception (master read) in master mode (PSR.WTDF)

If a wrong TDF code is found in TBUF, the error event is active until the TDF value is either corrected or invalidated. If the related interrupt is enabled, the interrupt handler should check PSR.WDTF first and correct or invalidate TBUF, before dealing with the other possible interrupt events.

14.5.2.8 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

14.5.2.9 Receiver Address Acknowledge

After a (repeated) start condition, the master sends a slave address to identify the target device of the communication. The start address can comprise one or two address bytes (for 7 bit or for 10 bit addressing schemes). After an address byte, a slave sensitive to the transmitted address has to acknowledge the reception.

Therefore, the slave's address can be programmed in the device, where it is compared to the received address. In case of a match, the slave answers with an acknowledge (SDA = 0). Slaves that are not targeted answer with a non-acknowledge (SDA = 1).

In addition to the match of the programmed address, another address byte value has to be answered with an acknowledge if the slave is capable to handle the corresponding requests. The address byte 00_H indicates a general call address, that can be acknowledged. The value 01_H stands for a start byte generation, that is not acknowledged

In order to allow selective acknowledges for the different values of the address byte(s), the following control mechanism is implemented:

- The address byte 00_H is acknowledged if bit PCR.ACK00 is set.
- The address byte 01_H is not acknowledged.
- The first 7 bits of a received first address byte are compared to the programmed slave address (PCR.SLAD[15:9]). If these bits match, the slave sends an acknowledge. In addition to this, if the slave address is programmed to 1111 0XX_B, the slave device waits for a second address byte and compares it also to PCR.SLAD[7:0] and sends an acknowledge accordingly to cover the 10 bit addressing mode. The user has to

Universal Serial Interface Channel (USIC)

take care about reserved addresses (refer to IIC specification for more detailed description). Only the address 1111 0XX₆ is supported.

Under each of these conditions, bit PSR.SLSEL will be set when the addressing delivered a match. This bit is cleared automatically by a (repeated) start condition.

14.5.2.10 Receiver Handling

A selected slave receiver always acknowledges a received data byte. If the receive buffers RBUF0/1 are already full and can not accept more data, the respective register is overwritten (PSR.DLI becomes set in this case and a protocol interrupt can be generated).

An address reception also uses the registers RBUF0/1 to store the address before checking if the device is selected. The received addresses do not set RDV0/1, so the addresses are not handled like received data.

14.5.2.11 Receiver Status Information

In addition to the received data byte, some IIC protocol related information is stored in the 16-bit data word of the receive buffer. The received data byte is available at the bit positions RBUF[7:0], whereas the additional information is monitored at the bit positions RBUF[12:8]. This structure allows to identify the meaning of each received data byte without reading additional registers, also when using a FIFO data buffer.

- RBUF[8]:
Value of the received acknowledge bit. This information is also available in RBUF[8] as protocol argument.
- RBUF[9]:
A 1 at this bit position indicates that after a (repeated) start condition followed by the address reception the first data byte of a new frame has been received. A 0 at this bit position indicates further data bytes. This information is also available in RBUF[9], allowing different interrupt routines for the address and data handling.
- RBUF[10]:
A 0 at this bit position indicates that the data byte has been received when the device has been in slave mode, whereas a 1 indicates a reception in master mode.
- RBUF[11]:
A 1 at this bit position indicates an incomplete/erroneous data byte in the receive buffer caused by a wrong position of a START or STOP condition in the frame. The bit is not identical to the frame error status bit in PSR, because the bit in the PSR has to be cleared by software ("sticky" bit), whereas RBUF[11] is evaluated data byte by data byte. If RBUF[11] = 0, the received data byte has been correct, independent of former errors.
- RBUF[12]:
A 0 at this bit position indicates that the programmed address has been received. A 1 indicates a general call address.

14.5.3 Symbol Timing

The symbol timing of the IIC is determined by the master stimulating the shift clock line SCL. It is different in each of the modes.

- 100 kBaud standard mode (PCR.STIM = 0):
The symbol timing is based on 10 time quanta t_q per symbol. A minimum module clock frequency $f_{\text{PERIPH}} = 2 \text{ MHz}$ is required.
- 400 kBaud fast mode (PCR.STIM = 1):
The symbol timing is based on 25 time quanta t_q per symbol. A minimum module clock frequency $f_{\text{PERIPH}} = 10 \text{ MHz}$ is required.

The baud rate setting should only be changed while the transmitter and the receiver are idle or CCR.MODE = 0. The bits in register BRG define the length of a time quantum t_q that is given by one period of f_{PCTQ} .

- BRG.CTQSEL
to define the input frequency f_{CTQIN} for the time quanta generation
- BRG.PCTQ
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4)
- BRG.DCTQ
to define the number of time quanta per symbol (number of $t_q = \text{DCTQ} + 1$)

The standard setting is given by CTQSEL = 00_B ($f_{\text{CTQIN}} = f_{\text{PDIV}}$) and PPPEN = 0 ($f_{\text{PPP}} = f_{\text{IN}}$). Under these conditions, the frequency f_{PCTQ} is given by:

$$f_{\text{PCTQ}} = f_{\text{PIN}} \times \frac{1}{\text{PDIV} + 1} \times \frac{1}{\text{PCTQ} + 1} \quad (14.10)$$

To respect the specified SDA hold time of 300 ns for standard mode and fast mode after a falling edge of signal SCL, a hold delay t_{HDEL} has been introduced. It also prevents an erroneous detection of a start or a stop condition. The length of this delay can be programmed by bit field PCR.HDEL. Taking into account the input sampling and output update, bit field HDEL can be programmed according to:

(14.11)

$$\begin{aligned} \text{HDEL} &\geq 300 \text{ ns} \times f_{\text{PPP}} - \left(3 \times \frac{f_{\text{PPP}}}{f_{\text{PERIPH}}} \right) + 1 && \text{with digital filter and HDELmin} = 2 \\ \text{HDEL} &\geq 300 \text{ ns} \times f_{\text{PPP}} - \left(3 \times \frac{f_{\text{PPP}}}{f_{\text{PERIPH}}} \right) + 2 && \text{without digital filter and HDELmin} = 1 \end{aligned}$$

If the digital input filter is used, HDEL compensates the filter delay of 2 filter periods (f_{PPP} should be used) in case of a spike on the input signal. This ensures that a data bit on the SDA line changing just before the rising edge or behind the falling edge of SCL will not be treated as a start or stop condition.

Universal Serial Interface Channel (USIC)

14.5.3.1 Start Symbol

Figure 14-52 shows the general start symbol timing.

Figure 14-52 Start Symbol Timing

14.5.3.2 Repeated Start Symbol

During the first part of a repeated start symbol, an SCL low value is driven for the specified number of time quanta. Then a high value is output. After the detection of a rising edge at the SCL input, a normal start symbol is generated, as shown in Figure 14-53.

Figure 14-53 Repeated Start Symbol Timing

14.5.3.3 Stop Symbol

Figure 14-54 shows the stop symbol timing.

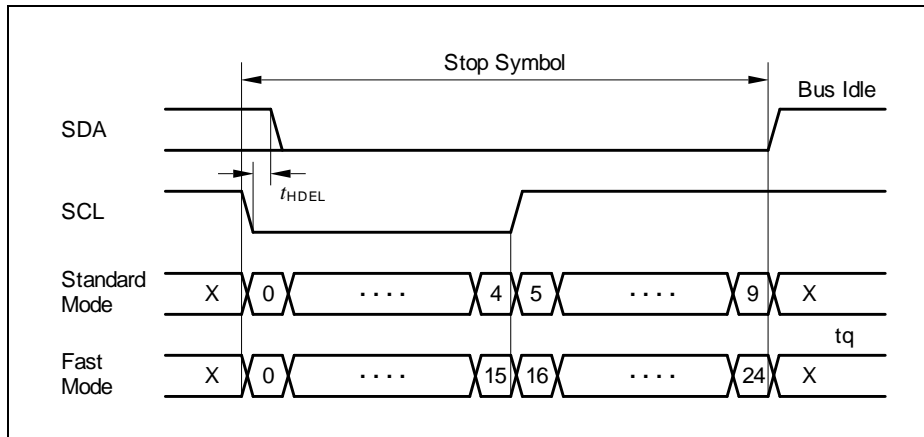

Figure 14-54 Stop Symbol Timing

14.5.3.4 Data Bit Symbol

Figure 14-55 shows the general data bit symbol timing.

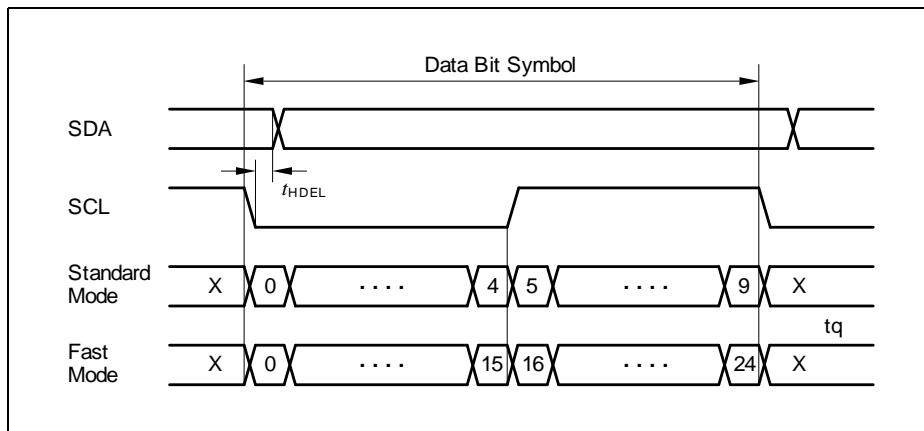

Figure 14-55 Data Bit Symbol

Output SDA changes after the time t_{HDEL} defined by PCR.HDEL has elapsed if a falling edge is detected at the SCL input to respect the SDA hold time. The value of PCR.HDEL allows compensation of the delay of the SCL input path (sampling, filtering).

Universal Serial Interface Channel (USIC)

In the case of an acknowledge transmission, the USIC IIC waits for the receiver indicating that a complete byte has been received. This adds an additional delay of 3 periods of f_{PERIPH} to the path. The minimum module input frequency has to be selected properly to ensure the SDA setup time to SCL rising edge.

14.5.4 Data Flow Handling

The handling of the data flow and the sequence of the symbols in an IIC frame is controlled by the IIC transmitter part of the USIC communication channel. The IIC bus protocol is byte-oriented, whereas a USIC data buffer word can contain up to 16 data bits. In addition to the data byte to be transmitted (located at TBUF[7:0]), bit field TDF (transmit data format) to control the IIC sequence is located at the bit positions TBUF[10:8]. The TDF code defines for each data byte how it should be transmitted (IIC master or IIC slave), and controls the transmission of (repeated) start and stop symbols. This structure allows the definition of a complete IIC frame for an IIC master device only by writing to TBUFx or by using a FIFO data buffer mechanism, because no other control registers have to be accessed. Alternatively, polling of the ACK and NACK bits in PSR register can be performed, and the next data byte is transmitted only after an ACK is received.

If a wrong or unexpected TDF code is encountered (e.g. due to a software error during setup of the transmit buffer), a stop condition will be sent out by the master. This leads to an abort of the currently running frame. A slave module waits for a valid TDF code and sets SCL = 0. The software then has to invalidate the unexpected TDF code and write a valid one.

Please note that during an arbitration phase in multi-master bus systems an unpredictable bus behavior may occur due to an unexpected stop condition.

14.5.4.1 Transmit Data Formats

The following transmit data formats are available in master mode:

Table 14-13 Master Transmit Data Formats

| TDF Code | Description |
|------------------|---|
| 000 _B | Send data byte as master This format is used to transmit a data byte from the master to a slave. The transmitter sends its data byte (TBUF[7:0]), receives and checks the acknowledge bit sent by the slave. |
| 010 _B | Receive data byte and send acknowledge This format is used by the master to read a data byte from a slave. The master acknowledges the transfer with a 0-level to continue the transfer. The content of TBUF[7:0] is ignored. |

Universal Serial Interface Channel (USIC)

Table 14-13 Master Transmit Data Formats (cont'd)

| TDF Code | Description |
|------------------|--|
| 011 _B | Receive data byte and send not-acknowledge This format is used by the master to read a data byte from a slave. The master does not acknowledge the transfer with a 1-level to finish the transfer. The content of TBUF[7:0] is ignored. |
| 100 _B | Send start condition If TBUF contains this entry while the bus is idle, a start condition will be generated. The content of TBUF[7:0] is taken as first address byte for the transmission (bits TBUF[7:1] are the address, the LSB is the read/write control). |
| 101 _B | Send repeated start condition If TBUF contains this entry and SCL = 0 and a byte transfer is not in progress, a repeated start condition will be sent out if the device is the current master. The current master is defined as the device that has set the start condition (and also won the master arbitration) for the current message. The content of TBUF[7:0] is taken as first address byte for the transmission (bits TBUF[7:1] are the address, the LSB is the read/write control). |
| 110 _B | Send stop condition If the current master has finished its last byte transfer (including acknowledge), it sends a stop condition if this format is in TBUF. The content of TBUF[7:0] is ignored. |
| 111 _B | Reserved This code must not be programmed. No additional action except releasing the TBUF entry and setting the error bit in PSR (that can lead to a protocol interrupt). |

The following transmit data format is available in slave mode (the symbols in a frame are controlled by the master and the slave only has to send data if it has been “asked” by the master):

Table 14-14 Slave Transmit Data Format

| TDF Code | Description |
|------------------|--|
| 001 _B | Send data byte as slave This format is used to transmit a data byte from a slave to the master. The transmitter sends its data byte (TBUF[7:0]) plus the acknowledge bit as a 1. |

Universal Serial Interface Channel (USIC)

14.5.4.2 Valid Master Transmit Data Formats

Due to the IIC frame format definitions, only some specific sequences of TDF codes are possible and valid. If the USIC IIC module detects a wrong TDF code in a running frame, the transfer is aborted and flag PCR.WTDF is set. Additionally, an interrupt can be generated if enabled by the user. In case of a wrong TDF code, the frame will be aborted immediately with a STOP condition if the USIC IIC master still owns the SDA line. But if the accessed slave owns the SDA line (read transfer), the master must perform a dummy read with a non-acknowledge so that the slave releases the SDA line before a STOP condition can be sent. The received data byte of the dummy read will be stored in RBUF0/1, but RDV0/1 will not be set. Therefore the dummy read will not generate a receive interrupt and the data byte will not be stored into the receive FIFO.

If the transfer direction has changed in the current frame (master read access), the transmit data request (TDF = 000_B) is not possible and won't be accepted (leading to a wrong TDF Code indication).

Table 14-15 Valid TDF Codes Overview

| Frame Position | Valid TDF Codes |
|--|--|
| First TDF code (master idle) | Start (100 _B) |
| Read transfer: second TDF code (after start or repeated start) | Receive with acknowledge (010 _B) or receive with not-acknowledge (011 _B) |
| Write transfer: second TDF code (after start or repeated start) | Transmit (000 _B), repeated start (101 _B), or stop (110 _B) |
| Read transfer: third and subsequent TDF code after acknowledge | Receive with acknowledge (010 _B) or receive with not-acknowledge (011 _B) |
| Read transfer: third and subsequent TDF code after not-acknowledge | Repeated start (101 _B) or stop (110 _B) |
| Write transfer: third and subsequent TDF code | Transmit (000 _B), repeated start (101 _B), or stop (110 _B) |

- First TDF code:
A master transfer starts with the TDF start code (100_B). All other codes are ignored, but no WTDF error will be indicated.
- TDF code after a start (100_B) or repeated start code (101_B) in case of a read access:
If a master-read transfer is started (determined by the LSB of the address byte = 1), the transfer direction of SDA changes and the slave will actively drive the data line. In this case, only the codes 010_B and 011_B are valid. To abort the transfer in case of a wrong code, a dummy read must be performed by the master before the STOP condition can be generated.

Universal Serial Interface Channel (USIC)

- TDF code after a start (100_B) or repeated start code (101_B) in case of a write access:
If a master-write transfer is started (determined by the LSB of the address byte = 0), the master still owns the SDA line. In this case, the transmit (000_B), repeated start (101_B) and stop (110_B) codes are valid. The other codes are considered as wrong. To abort the transfer in case of a wrong code, the STOP condition is generated immediately.
- TDF code of the third and subsequent command in case of a read access with acknowledged previous data byte:
If a master-read transfer is started (determined by the LSB of the address byte), the transfer direction of SDA changes and the slave will actively drive the data line. To force the slave to release the SDA line, the master has to not-acknowledge a byte transfer. In this case, only the receive codes 010_B and 011_B are valid. To abort the transfer in case of a wrong code, a dummy read must be performed by the master before the STOP condition can be generated.
- TDF code of the third and subsequent command in case of a read access with a not-acknowledged previous data byte:
If a master-read transfer is started (determined by the LSB of the address byte), the transfer direction of SDA changes and the slave will actively drive the data line. To force the slave to release the SDA line, the master has to not-acknowledge a byte transfer. In this case, only the restart (101_B) and stop code (110_B) are valid. To abort the transfer in case of a wrong code, the STOP condition is generated immediately.
- TDF code of the third and subsequent command in case of a write access:
If a master-write transfer is started (determined by the LSB of the address byte), the master still owns the SDA line. In this case, the transmit (000_B), repeated start (101_B) and stop (110_B) codes are valid. The other codes are considered as wrong. To abort the transfer in case of a wrong code, the STOP condition is generated immediately.
- After a master device has received a non-acknowledge from a slave device, a stop condition will be sent out automatically, except if the following TDF code requests a repeated start condition. In this case, the TDF code is taken into account, whereas all other TDF codes are ignored.

Universal Serial Interface Channel (USIC)

Figure 14-56 IIC Master Transmission

Universal Serial Interface Channel (USIC)
14.5.4.3 Master Transmit/Receive Modes

In master transmit mode, the IIC sends a number of data bytes to a slave receiver. The TDF code sequence for the master transmit mode is shown in [Table 14-16](#).

Table 14-16 TDF Code Sequence for Master Transmit

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|------------------------------------|------------------------------|--------------------------------|---|--|
| 1st code | 100 _B | Slave address + write bit | Send START condition, slave address and write bit | SCR: Indicates a START condition is detected TBIF: Next word can be written to TBUF |
| 2nd code | 000 _B | Data or 2nd slave address byte | Send data or 2nd slave address byte | TBIF: Next word can be written to TBUF |
| Subsequent codes for data transmit | 000 _B | Data | Send data | TBIF: Next word can be written to TBUF |
| Last code | 110 _B | Don't care | Send STOP condition | PCR: Indicates a STOP condition is detected |

In master receive mode, the IIC receives a number of data bytes from a slave transmitter. The TDF code sequence for the master receive 7-bit and 10-bit addressing modes are shown in [Table 14-17](#) and [Table 14-18](#).

Table 14-17 TDF Code Sequence for Master Receive (7-bit Addressing Mode)

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|--------------------------|------------------------------|--------------------------|--|--|
| 1st code | 100 _B | Slave address + read bit | Send START condition, slave address and read bit | SCR: Indicates a START condition is detected TBIF: Next word can be written to TBUF |
| 2nd code | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF AIF: First data received can be read |

Universal Serial Interface Channel (USIC)
Table 14-17 TDF Code Sequence for Master Receive (7-bit Addressing Mode)

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|-----------------------------------|------------------------------|------------------|--------------------------------|---|
| Subsequent codes for data receive | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF RIF: Subsequent data received can be read |
| Code for last data to be received | 011 _B | Don't care | Receive data and send NACK bit | TBIF: Next word can be written to TBUF RIF: Last data received can be read |
| Last code | 110 _B | Don't care | Send STOP condition | PCR: Indicates a STOP condition is detected |

Table 14-18 TDF Code Sequence for Master Receive (10-bit Addressing Mode)

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|-----------------------------------|------------------------------|--------------------------------------|--|--|
| 1st code | 100 _B | Slave address (1st byte) + write bit | Send START condition, slave address (1st byte) and write bit | SCR: Indicates a START condition is detected TBIF: Next word can be written to TBUF |
| 2nd code | 000 _B | Slave address (2nd byte) | Send address (2nd byte) | TBIF: Next word can be written to TBUF |
| 3rd code | 101 _B | 1st slave address + read bit | Send repeated START condition, slave address (1st byte) and read bit | RSCR: Indicates a repeated START condition is detected TBIF: Next word can be written to TBUF |
| 4th code | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF AIF: First data received can be read |
| Subsequent codes for data receive | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF RIF: Subsequent data received can be read |

Universal Serial Interface Channel (USIC)

Table 14-18 TDF Code Sequence for Master Receive (10-bit Addressing Mode)

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|-----------------------------------|-----------------------|------------|--------------------------------|--|
| Code for last data to be received | 011 _B | Don't care | Receive data and send NACK bit | TBIF: Next word can be written to TBUF RIF: Last data received from slave can be read |
| Last code | 110 _B | Don't care | Send STOP condition | PCR: Indicates a STOP condition is detected |

Figure 14-57 shows the interrupt events during the master transmit-slave receive and master receive/slave transmit sequences.

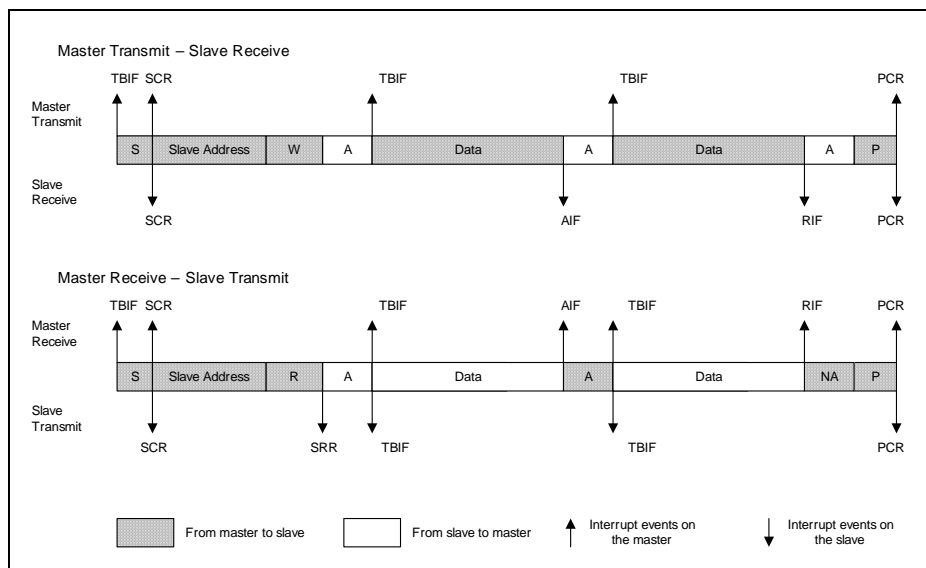

Figure 14-57 Interrupt Events on Data Transfers

14.5.4.4 Slave Transmit/Receive Modes

In slave receive mode, no TDF code needs to be written and data reception is indicated by the alternate receive (AIF) or receive (RIF) events.

In slave transmit mode, upon receiving its own slave address or general call address if this option is enabled, a slave read request event (SRR) will be triggered. The slave IIC then writes the TDF code 001_B and the requested data to TBUF to transmit the data to

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|------|------|--|
| STIM | 17 | rw | Symbol Timing This bit defines how many time quanta are used in a symbol. 0 _B A symbol contains 10 time quanta. The timing is adapted for standard mode (100 kBaud). 1 _B A symbol contains 25 time quanta. The timing is adapted for fast mode (400 kBaud). |
| SCRIEN | 18 | rw | Start Condition Received Interrupt Enable This bit enables the generation of a protocol interrupt if a start condition is detected. 0 _B The start condition interrupt is disabled. 1 _B The start condition interrupt is enabled. |
| RSCRIEN | 19 | rw | Repeated Start Condition Received Interrupt Enable This bit enables the generation of a protocol interrupt if a repeated start condition is detected. 0 _B The repeated start condition interrupt is disabled. 1 _B The repeated start condition interrupt is enabled. |
| PCRIEN | 20 | rw | Stop Condition Received Interrupt Enable This bit enables the generation of a protocol interrupt if a stop condition is detected. 0 _B The stop condition interrupt is disabled. 1 _B The stop condition interrupt is enabled. |
| NACKIEN | 21 | rw | Non-Acknowledge Interrupt Enable This bit enables the generation of a protocol interrupt if a non-acknowledge is detected by a master. 0 _B The non-acknowledge interrupt is disabled. 1 _B The non-acknowledge interrupt is enabled. |
| ARLIEN | 22 | rw | Arbitration Lost Interrupt Enable This bit enables the generation of a protocol interrupt if an arbitration lost event is detected. 0 _B The arbitration lost interrupt is disabled. 1 _B The arbitration lost interrupt is enabled. |
| SRRIEN | 23 | rw | Slave Read Request Interrupt Enable This bit enables the generation of a protocol interrupt if a slave read request is detected. 0 _B The slave read request interrupt is disabled. 1 _B The slave read request interrupt is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| ERRIEN | 24 | rw | Error Interrupt Enable This bit enables the generation of a protocol interrupt if an IIC error condition is detected (indicated by PSR.ERR or PSR.WTDF). 0 _B The error interrupt is disabled. 1 _B The error interrupt is enabled. |
| SACKDIS | 25 | rw | Slave Acknowledge Disable This bit disables the generation of an active acknowledge signal for a slave device (active acknowledge = 0 level). Once set by software, it is automatically cleared with each (repeated) start condition. If this bit is set after a byte has been received (indicated by an interrupt) but before the next acknowledge bit has started, the next acknowledge bit will be sent with passive level. This would indicate that the receiver does not accept more bytes. As a result, a minimum of 2 bytes will be received if the first receive interrupt is used to set this bit. 0 _B The generation of an active slave acknowledge is enabled (slave acknowledge with 0 level = more bytes can be received). 1 _B The generation of an active slave acknowledge is disabled (slave acknowledge with 1 level = reception stopped). |
| HDEL | [29:26] | rw | Hardware Delay This bit field defines the delay used to compensate the internal treatment of the SCL signal (see Page 14-118) in order to respect the SDA hold time specified for the IIC protocol. |
| ACKIEN | 30 | rw | Acknowledge Interrupt Enable This bit enables the generation of a protocol interrupt if an acknowledge is detected by a master. 0 _B The acknowledge interrupt is disabled. 1 _B The acknowledge interrupt is enabled. |
| MCLK | 31 | rw | Master Clock Enable This bit enables generation of the master clock MCLK (not directly used for IIC protocol, can be used as general frequency output). 0 _B The MCLK generation is disabled and MCLK is 0. 1 _B The MCLK generation is enabled. |

Universal Serial Interface Channel (USIC)
14.5.5.2 IIC Protocol Status Register

The following PSR status bits or bit fields are available in IIC mode. Please note that the bits in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. These flags should be cleared by software before enabling a new protocol.

PSR
Protocol Status Register [IIC Mode] (48_H)
Reset Value: 0000 0000_H

| rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh | rwh |

| Field | Bits | Type | Description |
|--------------|------|------|--|
| SLSEL | 0 | rwh | Slave Select This bit indicates that this device has been selected as slave. 0 _B The device is not selected as slave. 1 _B The device is selected as slave. |
| WTDF | 1 | rwh | Wrong TDF Code Found¹⁾ This bit indicates that an unexpected/wrong TDF code has been found. A protocol interrupt can be generated if PCR.ERRIEN = 1. 0 _B A wrong TDF code has not been found. 1 _B A wrong TDF code has been found. |
| SCR | 2 | rwh | Start Condition Received¹⁾ This bit indicates that a start condition has been detected on the IIC bus lines. A protocol interrupt can be generated if PCR.SCRIEN = 1. 0 _B A start condition has not yet been detected. 1 _B A start condition has been detected. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|------|------|--|
| RSCR | 3 | rwh | Repeated Start Condition Received¹⁾ This bit indicates that a repeated start condition has been detected on the IIC bus lines. A protocol interrupt can be generated if PCR.RSCRIEN = 1. 0 _B A repeated start condition has not yet been detected. 1 _B A repeated start condition has been detected. |
| PCR | 4 | rwh | Stop Condition Received¹⁾ This bit indicates that a stop condition has been detected on the IIC bus lines. A protocol interrupt can be generated if PCR.PCRIEN = 1. 0 _B A stop condition has not yet been detected. 1 _B A stop condition has been detected. |
| NACK | 5 | rwh | Non-Acknowledge Received¹⁾ This bit indicates that a non-acknowledge has been received in master mode. This bit is not set in slave mode. A protocol interrupt can be generated if PCR.NACKIEN = 1. 0 _B A non-acknowledge has not been received. 1 _B A non-acknowledge has been received. |
| ARL | 6 | rwh | Arbitration Lost¹⁾ This bit indicates that an arbitration has been lost. A protocol interrupt can be generated if PCR.ARLIEN = 1. 0 _B An arbitration has not been lost. 1 _B An arbitration has been lost. |
| SRR | 7 | rwh | Slave Read Request¹⁾ This bit indicates that a slave read request has been detected. It becomes active to request the first data byte to be made available in the transmit buffer. For further consecutive data bytes, the transmit buffer issues more interrupts. For the end of the transfer, the master transmitter sends a stop condition. A protocol interrupt can be generated if PCR.SRRIEN = 1. 0 _B A slave read request has not been detected. 1 _B A slave read request has been detected. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| ERR | 8 | rwh | Error¹⁾ This bit indicates that an IIC error (frame format or TDF code) has been detected. A protocol interrupt can be generated if PCR.ERRIEN = 1. 0 _B An IIC error has not been detected. 1 _B An IIC error has been detected. |
| ACK | 9 | rwh | Acknowledge Received¹⁾ This bit indicates that an acknowledge has been received in master mode. This bit is not set in slave mode. A protocol interrupt can be generated if PCR.ACKIEN = 1. 0 _B An acknowledge has not been received. 1 _B An acknowledge has been received. |
| RSIF | 10 | rwh | Receiver Start Indication Flag 0 _B A receiver start event has not occurred. 1 _B A receiver start event has occurred. |
| DLIF | 11 | rwh | Data Lost Indication Flag 0 _B A data lost event has not occurred. 1 _B A data lost event has occurred. |
| TSIF | 12 | rwh | Transmit Shift Indication Flag 0 _B A transmit shift event has not occurred. 1 _B A transmit shift event has occurred. |
| TBIF | 13 | rwh | Transmit Buffer Indication Flag 0 _B A transmit buffer event has not occurred. 1 _B A transmit buffer event has occurred. |
| RIF | 14 | rwh | Receive Indication Flag 0 _B A receive event has not occurred. 1 _B A receive event has occurred. |
| AIF | 15 | rwh | Alternative Receive Indication Flag 0 _B An alternative receive event has not occurred. 1 _B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0 _B A baud rate generator event has not occurred. 1 _B A baud rate generator event has occurred. |
| 0 | [31:17] | r | Reserved Returns 0 if read; not modified in IIC mode. |

1) This status bit can generate a protocol interrupt (see [Page 14-22](#)). The general interrupt status flags are described in the general interrupt chapter.

Universal Serial Interface Channel (USIC)

14.6 Inter-IC Sound Bus Protocol (IIS)

This chapter describes how the USIC module handles the IIS protocol. This serial protocol can handle reception and transmission of synchronous data frames between a device operating in master mode and a device in slave mode. An IIS connection based on a USIC communication channel supports half-duplex and full-duplex data transfers. The IIS mode is selected by $CCR.MODE = 0011_B$ with $CCFG.IIS = 1$ (IIS mode is available).

14.6.1 Introduction

The IIS protocol is a synchronous serial communication protocol mainly for audio and infotainment applications [8].

14.6.1.1 Signal Description

A connection between an IIS master and an IIS slave is based on the following signals:

- A shift clock signal SCK, generated by the transfer master. It is permanently generated while an IIS connection is established, also while no valid data bits are transferred.
- A word address signal WA (also named WS), generated by the transfer master. It indicates the beginning of a new data word and the targeted audio channel (e.g. left/right). The word address output signal WA is available on all SELOx outputs if the WA generation is enabled (by $PCR.WAGEN = 1$ for the transfer master). The WA signal changes synchronously to the falling edges of the shift clock.
- If the transmitter is the IIS master device, it generates a master transmit slave receive data signal. The data changes synchronously to the falling edges of the shift clock.
- If the transmitter is the IIS slave device, it generates a master receive slave transmit data signal. The data changes synchronously to the falling edges of the shift clock.

The transmitter part and the receiver part of the USIC communication channel can be used together to establish a full-duplex data connection between an IIS master and a slave device.

Table 14-19 IIS IO Signals

| IIS Mode | Receive Data | Transmit Data | Shift Clock | Word Address |
|----------|-------------------------------|---------------|---------------------------------|--------------------------------|
| Master | Input DIN0, handled by DX0 | Output DOUT0 | Output SCLKOUT | Output(s) SELOx |

Universal Serial Interface Channel (USIC)

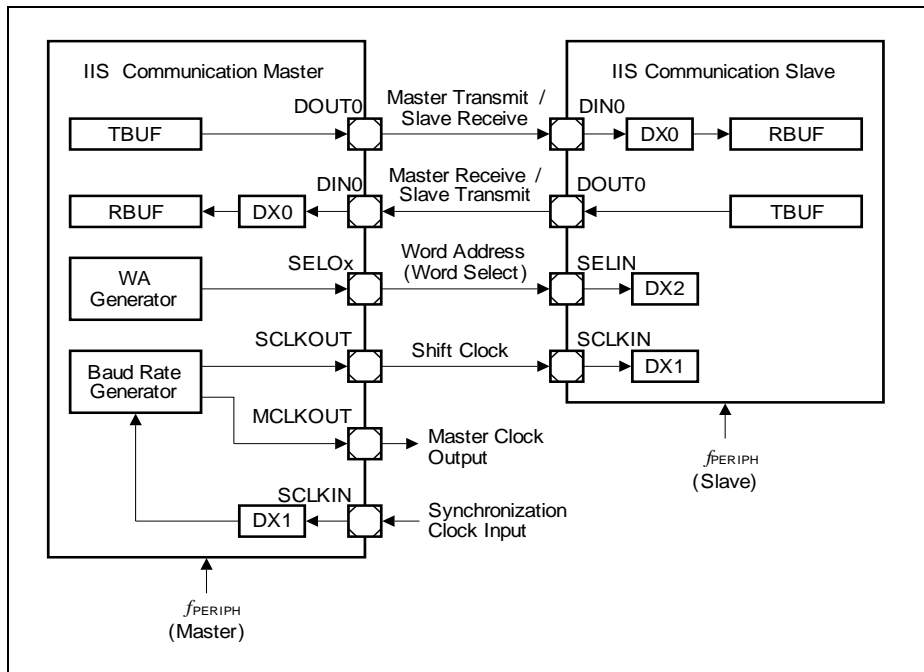

Figure 14-58 IIS Signals

Two additional signals are available for the USIC IIS communication master:

- A master clock output signal **MCLKOUT** with a fixed phase relation to the shift clock to support oversampling for audio components. It can also be used as master clock output of a communication network with synchronized IIS connections.
- A synchronization clock input **SCLKIN** for synchronization of the shift clock generation to an external frequency to support audio frequencies that can not be directly derived from the system clock f_{PERIPH} of the communication master. It can be used as master clock input of a communication network with synchronized IIS connections.

14.6.1.2 Protocol Overview

An IIS connection supports transfers for two different data frames via the same data line, e.g. a data frames for the left audio channel and a data frame for the right audio channel. The word address signal **WA** is used to distinguish between the different data frames. Each data frame can consist of several data words.

Universal Serial Interface Channel (USIC)

In a USIC communication channel, data words are tagged for being transmitted for the left or for the right channel. Also the received data words contain a tag identifying the WA state when the data has been received.

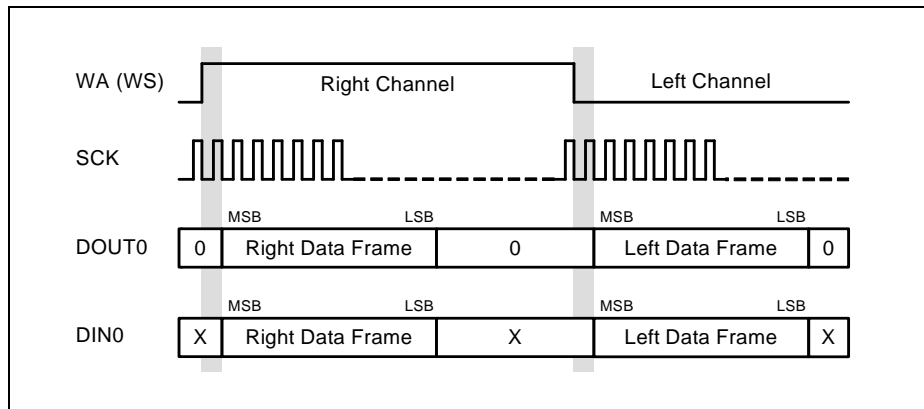

Figure 14-59 Protocol Overview

14.6.1.3 Transfer Delay

The transfer delay feature allows the transfer of data (transmission and reception) with a programmable delay (counted in shift clock periods).

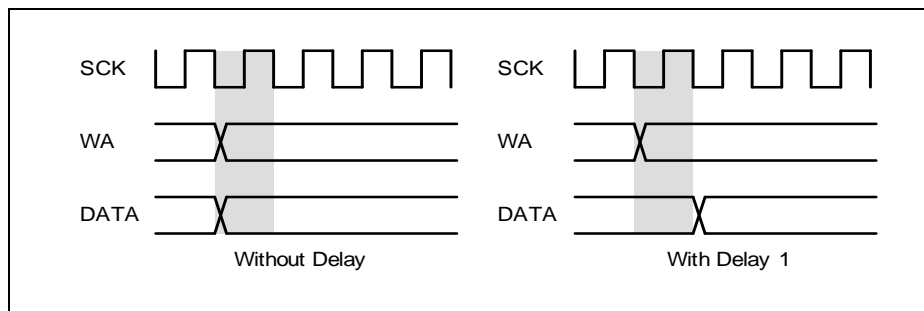

Figure 14-60 Transfer Delay for IIS

14.6.1.4 Connection of External Audio Components

The IIS signals can be used to communicate with external audio devices (such as Codecs) or other audio data sources/destinations.

Figure 14-61 Connection of External Audio Devices

In some applications, especially for Audio-ADCs or Audio-DACs, a master clock signal is required with a fixed phase relation to the shift clock signal. The frequency of MCLKOUT is a multiple of the shift frequency SCLKOUT. This factor defines the oversampling factor of the external device (commonly used values: 256 or 384).

14.6.2 Operating the IIS

This chapter contains IIS issues, that are of general interest and not directly linked to master mode or slave mode.

14.6.2.1 Frame Length and Word Length Configuration

After each change of the WA signal, a complete data frame is intended to be transferred (frame length \leq system word length). The number of data bits transferred after a change of signal WA is defined by SCTR.FLE. A data frame can consist of several data words with a data word length defined by SCTR.WLE. The changes of signal WA define the system word length as the number of SCLK cycles between two changes of WA (number of bits available for the right channel and same number available for the left channel).

If the system word length is longer than the frame length defined by SCTR.FLE, the additional bits are transmitted with passive data level (SCTR.PDL). If the system word

Universal Serial Interface Channel (USIC)

length is smaller than the device frame length, not all LSBs of the transmit data can be transferred.

It is recommended to program bits WLEMD, FLEMD and SELMD in register TCSR to 0.

14.6.2.2 Automatic Shadow Mechanism

The baud rate and shift control setting are internally kept constant while a data frame is transferred by an automatic shadow mechanism. The registers can be programmed all the time with new settings that are taken into account for the next data frame. During a data frame, the applied (shadowed) setting is not changed, although new values have been written after the start of the data frame. The setting is internally “frozen” with the start of each data frame.

Although this shadow mechanism being implemented, it is recommended to change the baud rate and shift control setting only while the IIS protocol is switched off.

14.6.2.3 Mode Control Behavior

In IIS mode, the following kernel modes are supported:

- Run Mode 0/1:
Behavior as programmed, no impact on data transfers.
- Stop Mode 0/1:
Bit PCR.WAGEN is internally considered as 0 (the bit itself is not changed). If WAGEN = 1, the WA generation is stopped, but PSR.END is not set. The complete data frame is finished before entering stop mode, including a possible delay due to PCR.TDEL.
When leaving a stop mode with WAGEN = 1, the WA generation starts from the beginning.

14.6.2.4 Transfer Delay

The transfer delay can be used to synchronize a data transfer to an event (e.g. a change of the WA signal). This event has to be synchronously generated to the falling edge of the shift clock SCK (like the change of the transmit data), because the input signal for the event is directly sampled in the receiver (as a result, the transmitter can use the detection information with its next edge).

Event signals that are asynchronous to the shift clock while the shift clock is running must not be used. In the example in [Figure 14-60](#), the event (change of signal WA) is generated by the transfer master and as a result, is synchronous to the shift clock SCK. With the rising edge of SCK, signal WA is sampled and checked for a change. If a change is detected, a transfer delay counter TDC is automatically loaded with its programmable reload value (PCR.TDEL), otherwise it is decremented with each rising edge of SCK until it reaches 0, where it stops. The transfer itself is started if the value of TDC has become 0. This can happen under two conditions:

Universal Serial Interface Channel (USIC)

- TDC is reloaded with a PCR.TDEL = 0 when the event is detected
- TDC has reached 0 while counting down

The transfer delay counter is internal to the IIS protocol pre-processor and can not be observed by software. The transfer delay in SCK cycles is given by PCR.TDEL+1.

In the example in [Figure 14-62](#), the reload value PCR.TDEL for TDC is 0. When the samples taken on receiver side show the change of the WA signal, the counter TDC is reloaded. If the reload value is 0, the data transfer starts with 1 shift clock cycle delay compared to the change of WA.

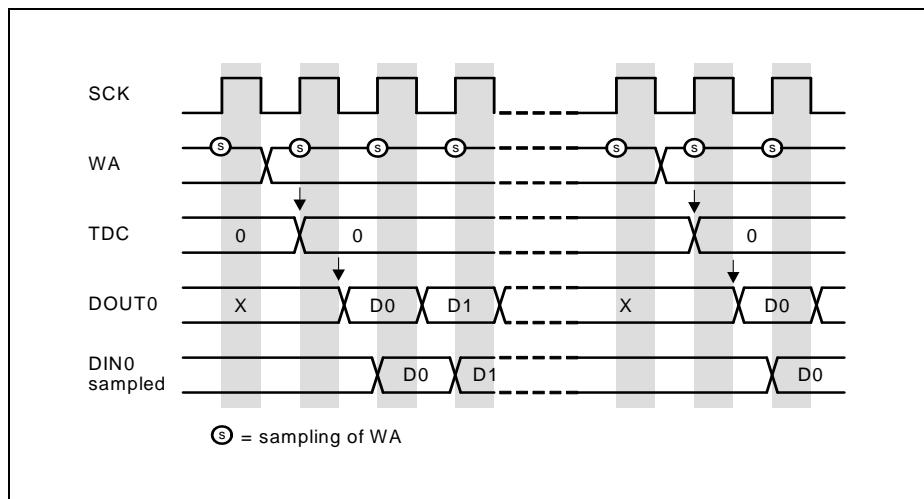

Figure 14-62 Transfer Delay with Delay 1

The ideal case without any transfer delay is shown in [Figure 14-63](#). The WA signal changes and the data output value become valid at the same time. This implies that the transmitter “knows” in advance that the event signal will change with the next rising edge of TCLK. This is achieved by delaying the data transmission after the previously detected WA change the system word length minus 1.

Figure 14-63 No Transfer Delay

If the end of the transfer delay is detected simultaneously to change of WA, the transfer is started and the delay counter is reloaded with PCR.TDEL. This allows to run the USIC as IIS device without any delay. In this case, internally the delay from the previous event elapses just at the moment when a new event occurs. If PCR.TDEL is set to a value bigger than the system word length, no transfer takes place.

14.6.2.5 Parity Mode

Parity generation is not supported in IIS mode and bit field CCR.PM = 00_B has to be programmed.

14.6.2.6 Transfer Mode

In IIS mode, bit field SCTR.TRM = 11_B has to be programmed to allow data transfers. Setting SCTR.TRM = 00_B disables and stops the data transfer immediately.

14.6.2.7 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to IIS frame handling.

- Transmit buffer interrupt TBI:
Bit PSR.TBIF is set after the start of first data bit of a data word.
- Transmit shift interrupt TSI:
Bit PSR.TSIF is set after the start of the last data bit of a data word.

Universal Serial Interface Channel (USIC)

- Receiver start interrupt RSI:
Bit PSR.RSIF is set after the reception of the first data bit of a data word.
With this event, bit TCSR.TDV is cleared and new data can be loaded to the transmit buffer.
- Receiver interrupt RI and alternative interrupt AI:
Bit PSR.RIF is set at after the reception of the last data bit of a data word with WA = 0.
Bit RBUF SR.SOF indicates whether the received data word has been the first data word of a new data frame.
Bit PSR.AIF is set at after the reception of the last data bit of a data word with WA = 1.
Bit RBUF SR.SOF indicates whether the received data word has been the first data word of a new data frame.

14.6.2.8 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

14.6.2.9 Protocol-Related Argument and Error

In order to distinguish between data words received for the left or the right channel, the IIS protocol pre-processor samples the level of the WA input (just after the WA transition) and propagates it as protocol-related error (although it is not an error, but an indication) to the receive buffer status register at the bit position RBUF SR[9]. This bit position defines if either a standard receive interrupt (if RBUF SR[9] = 0) or an alternative receive interrupt (if RBUF SR[9] = 1) becomes activated when a new data word has been received. Incoming data can be handled by different interrupts for the left and the right channel if the corresponding events are directed to different interrupt nodes. Flag PAR is always 0.

14.6.2.10 Transmit Data Handling

The IIS protocol pre-processor allows to distinguish between the left and the right channel for data transmission. Therefore, bit TCSR.WA indicates on which channel the data in the buffer will be transmitted. If TCSR.WA = 0, the data will be transmitted after a falling edge of WA. If TCSR.WA = 1, the data will be transmitted after a rising edge of WA. The WA value sampled after the WA transition is considered to distinguish between both channels (referring to PSR.WA).

Bit TCSR.WA can be automatically updated by the transmit control information TCI[4] for each data word if TCSR.WAMD = 1. In this case, data written to TBUF[15:0] (or IN[15:0] if a FIFO data buffer is used) is considered as left channel data, whereas data written to TBUF[31:16] (or IN[31:16] if a FIFO data buffer is used) is considered as right channel data.

14.6.2.11 Receive Buffer Handling

If a receive FIFO buffer is available (CCFG.RB = 1) and enabled for data handling (RBCTR.SIZE > 0), it is recommended to set RBCTR.RCIM = 11_B in IIS mode. This leads to an indication that the data word has been the first data word of a new data frame if bit OUTR.RCI[0] = 1, and the channel indication by the sampled WA value is given by OUTR.RCI[4].

The standard receive buffer event and the alternative receive buffer event can be used for the following operation in RCI mode (RBCTR.RNM = 1):

- A standard receive buffer event indicates that a data word can be read from OUTR that belongs to a data frame started when WA = 0.
- An alternative receive buffer event indicates that a data word can be read from OUTR that belongs to a data frame started when WA = 1.

14.6.2.12 Loop-Delay Compensation

The synchronous signaling mechanism of the IIS protocol being similar to the one of the SSC protocol, the closed-loop delay has to be taken into account for the application setup. In IIS mode, loop-delay compensation in master mode is also possible to achieve higher baud rates.

Please refer to the more detailed description in the SSC chapter.

14.6.3 Operating the IIS in Master Mode

In order to operate the IIS in master mode, the following issues have to be considered:

- Select IIS mode:
It is recommended to configure all parameters of the IIS that do not change during run time while CCR.MODE = 0000_B. Bit field SCTR.TRM = 11_B has to be programmed. The configuration of the input stages has to be done while CCR.MODE = 0000_B to avoid unintended edges of the input signals and the IIS mode can be enabled by CCR.MODE = 0011_B afterwards.
- Pin connection for data transfer:
Establish a connection of input stage DX0 with the selected receive data input pin (DIN0) with DX0CR.INSW = 1. Configure a transmit data output pin (DOUT0) for a transmitter.
The data shift unit allowing full-duplex data transfers based on the same WA signal, the values delivered by the DX0 stage are considered as data bits (receive function can not be disabled independently from the transmitter). To receive IIS data, the transmitter does not necessarily need to be configured (no assignment of DOUT0 signal to a pin).
- Baud rate generation:
The desired baud rate setting has to be selected, comprising the fractional divider

Universal Serial Interface Channel (USIC)

and the baud rate generator. Bit DX1CR.INSW = 0 has to be programmed to use the baud rate generator output SCLK directly as input for the data shift unit.

- **Word address WA generation:**
The WA generation has to be enabled by setting PCR.WAGEN = 1 and the programming of the number of shift clock cycles between the changes of WA. Bit DX2CR.INSW = 0 has to be programmed to use the WA generator as input for the data shift unit. Configure WA output pin for signal SELOx if needed.
- **Data format configuration:**
The word length, the frame length, and the shift direction have to be set up according to the application requirements by programming the register SCTR. Generally, the MSB is shifted first (SCTR.SDIR = 1).
Bit TCSR.WAMD can be set to use the transmit control information TCI[4] to distinguish the data words for transmission while WA = 0 or while WA = 1.

Note: The step to enable the alternate output port functions should only be done after the IIS mode is enabled, to avoid unintended spikes on the output.

14.6.3.1 Baud Rate Generation

The baud rate is defined by the frequency of the SCLK signal (one period of f_{SCLK} represents one data bit).

If the fractional divider mode is used to generate f_{PIN} , there can be an uncertainty of one period of f_{PERIPH} for f_{PIN} . This uncertainty does not accumulate over several SCLK cycles. As a consequence, the average frequency is reached, whereas the duty cycle of 50% of the SCLK and MCLK signals can vary by one period of f_{PERIPH} .

In IIS applications, where the phase relation between the optional MCLK output signal and SCLK is not relevant, SCLK can be based on the frequency f_{PIN} (BRG.PPPEN = 0). In the case that a fixed phase relation between the MCLK signal and SCLK is required (e.g. when using MCLK as clock reference for external devices), the additional divider by 2 stage has to be taken into account (BRG.PPPEN = 1). This division is due to the fact that signal MCLK toggles with each cycle of f_{PIN} . Signal SCLK is then based on signal MCLK, see [Figure 14-64](#).

The adjustable integer divider factor is defined by bit field BRG.PDIV.

$$\begin{aligned} f_{SCLK} &= \frac{f_{PIN}}{2} \times \frac{1}{PDIV + 1} & \text{if } PPPEN = 0 \\ f_{SCLK} &= \frac{f_{PIN}}{2 \times 2} \times \frac{1}{PDIV + 1} & \text{if } PPPEN = 1 \end{aligned} \quad (14.12)$$

Note: In the IIS protocol, the master (unit generating the shift clock and the WA signal) changes the status of its data and WA output line with the falling edge of SCK. The slave transmitter also has to transmit on falling edges. The sampling of the received data is done with the rising edges of SCLK. The input stage DX1 and the

Universal Serial Interface Channel (USIC)

SCLKOUT have to be programmed to invert the shift clock signal to fit to the internal signals.

14.6.3.2 WA Generation

The word address (or word select) line WA regularly toggles after N cycles of signal SCLK. The time between the changes of WA is called system word length and can be programmed by using the following bit fields.

In IIS master mode, the system word length is defined by:

- BRG.CTQSEL = 10_B
to base the WA toggling on SCLK
- BRG.PCTQ
to define the number N of SCLK cycles per system word length
- BRG.DCTQ
to define the number N of SCLK cycles per system word length

$$N = (PCTQ + 1) \times (DCTQ + 1) \quad (14.13)$$

14.6.3.3 Master Clock Output

The master clock signal MCLK can be generated by the master of the IIS transfer (BRG.PPPEN = 1). It is used especially to connect external Codec devices. It can be configured by bit BRG.MCLKCFG in its polarity to become the output signal MCLKOUT.

Figure 14-64 MCLK and SCLK for IIS

14.6.3.4 Protocol Interrupt Events

The following protocol-related events are generated in IIS mode and can lead to a protocol interrupt.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- **WA rising/falling edge events:**
The WA generation block indicates two events that are monitored in register PSR. Flag PSR.WAFE is set with the falling edge, flag PSR.WARE with the rising edge of the WA signal. A protocol interrupt can be generated if PCR.WAFEIEN = 1 for the falling edge, similar for PCR.WAREIEN = 1 for a rising edge.
- **WA end event:**
The WA generation block also indicates when it has stopped the WA generation after it has been disabled by writing PCR.WAGEN = 0. A protocol interrupt can be generated if PCR.ENDIEN = 1.
- **DX2T event:**
An activation of the trigger signal DX2T is indicated by PSR.DX2TEV = 1 and can generate a protocol interrupt if PCR.DX2TIEN = 1. This event can be evaluated instead of the WA rising/falling events if a delay compensation like in SSC mode (for details, refer to corresponding SSC section) is used.

14.6.4 Operating the IIS in Slave Mode

In order to operate the IIS in slave mode, the following issues have to be considered:

- **Select IIS mode:**
It is recommended to configure all parameters of the IIS that do not change during run time while CCR.MODE = 0000_B. Bit field SCTR.TRM = 11_B has to be programmed. The configuration of the input stages has to be done while CCR.MODE = 0000_B to avoid unintended edges of the input signals and the IIS mode can be enabled by CCR.MODE = 0011_B afterwards.
- **Pin connection for data transfer:**
Establish a connection of input stage DX0 with the selected receive data input pin (DIN0) with DX0CR.INSW = 1. Configure a transmit data output pin (DOUT0) for a transmitter.
The data shift unit allowing full-duplex data transfers based on the same WA signal, the values delivered by the DX0 stage are considered as data bits (receive function can not be disabled independently from the transmitter). To receive IIS data, the transmitter does not necessarily need to be configured (no assignment of DOUT0 signal to a pin).
Note that the step to enable the alternate output port functions should only be done after the IIS mode is enabled, to avoid unintended spikes on the output.

Universal Serial Interface Channel (USIC)

- Pin connection for shift clock:
Establish a connection of input stage DX1 with the selected shift clock input pin (SCLKIN) with DX1CR.INSW = 1 and with inverted polarity (DX1CR.DPOL = 1).
- Pin connection for WA input:
Establish a connection of input stage DX2 with the WA input pin (SELIN) with DX2CR.INSW = 1.
- Baud rate generation:
The baud rate generator is not needed and can be switched off by the fractional divider.
- WA generation:
The WA generation is not needed and can be switched off (PCR.WAGEN = 0).

14.6.4.1 Protocol Events and Interrupts

The following protocol-related event is generated in IIS mode and can lead to a protocol interrupt.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- WA rising/falling/end events:
The WA generation being switched off, these events are not available.
- DX2T event:
An activation of the trigger signal DX2T is indicated by PSR.DX2TEV = 1 and can generate a protocol interrupt if PCR.DX2TIEN = 1.

14.6.5 IIS Protocol Registers

In IIS mode, the registers PCR and PSR handle IIS related information.

14.6.5.1 IIS Protocol Control Registers

In IIS mode, the PCR register bits or bit fields are defined as described in this section.

Universal Serial Interface Channel (USIC)

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|------|------|---|
| SELINV | 2 | rw | Select Inversion This bit defines if the polarity of the SELOx outputs in relation to the internally generated word address signal WA. 0 _B The SELOx outputs have the same polarity as the WA signal. 1 _B The SELOx outputs have the inverted polarity to the WA signal. |
| WAFEIEN | 4 | rw | WA Falling Edge Interrupt Enable This bit enables/disables the activation of a protocol interrupt when a falling edge of WA has been generated. 0 _B A protocol interrupt is not activated if a falling edge of WA is generated. 1 _B A protocol interrupt is activated if a falling edge of WA is generated. |
| WAREIEN | 5 | rw | WA Rising Edge Interrupt Enable This bit enables/disables the activation of a protocol interrupt when a rising edge of WA has been generated. 0 _B A protocol interrupt is not activated if a rising edge of WA is generated. 1 _B A protocol interrupt is activated if a rising edge of WA is generated. |
| ENDIEN | 6 | rw | END Interrupt Enable This bit enables/disables the activation of a protocol interrupt when the WA generation stops after clearing PCR.WAGEN (complete system word length is processed before stopping). 0 _B A protocol interrupt is not activated. 1 _B A protocol interrupt is activated. |
| DX2TIEN | 15 | rw | DX2T Interrupt Enable This bit enables/disables the generation of a protocol interrupt if the DX2T signal becomes activated (indicated by PSR.DX2TEV = 1). 0 _B A protocol interrupt is not generated if DX2T is active. 1 _B A protocol interrupt is generated if DX2T is active. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|--------------------|------|--|
| TDEL | [21:16] | rw | Transfer Delay This bit field defines the transfer delay when an event is detected. If bit field TDEL = 0, the additional delay functionality is switched off and a delay of one shift clock cycle is introduced. |
| MCLK | 31 | rw | Master Clock Enable This bit enables generation of the master clock MCLK (not directly used for IIC protocol, can be used as general frequency output). 0 _B The MCLK generation is disabled and MCLK is 0. 1 _B The MCLK generation is enabled. |
| 0 | 3, [14:7], [30:22] | rw | Reserved Returns 0 if read; should be written with 0; |

14.6.5.2 IIS Protocol Status Register

The following PSR status bits or bit fields are available in IIS mode. Please note that the bits in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. These flags should be cleared by software before enabling a new protocol.

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|------|------|--|
| WA | 0 | rwh | Word Address This bit indicates the status of the WA input signal, sampled after a transition of WA has been detected. This information is forwarded to the corresponding bit position RBUFSTR[9] to distinguish between data received for the right and the left channel. 0_B WA has been sampled 0. 1_B WA has been sampled 1. |
| DX2S | 1 | rwh | DX2S Status This bit indicates the current status of the DX2S signal, which is used as word address signal WA. 0_B DX2S is 0. 1_B DX2S is 1. |
| DX2TEV | 3 | rwh | DX2T Event Detected¹⁾ This bit indicates that the DX2T signal has been activated. In IIS slave mode, an activation of DX2T generates a protocol interrupt if PCR.DX2TIEN = 1. 0_B The DX2T signal has not been activated. 1_B The DX2T signal has been activated. |
| WAFE | 4 | rwh | WA Falling Edge Event¹⁾ This bit indicates that a falling edge of the WA output signal has been generated. This event generates a protocol interrupt if PCR.WAFEIEN = 1. 0_B A WA falling edge has not been generated. 1_B A WA falling edge has been generated. |
| WARE | 5 | rwh | WA Rising Edge Event¹⁾ This bit indicates that a rising edge of the WA output signal has been generated. This event generates a protocol interrupt if PCR.WAREIEN = 1. 0_B A WA rising edge has not been generated. 1_B A WA rising edge has been generated. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|----------------------|------|---|
| END | 6 | rwh | WA Generation End¹⁾ This bit indicates that the WA generation has ended after clearing PCR.WAGEN. This bit should be cleared by software before clearing WAGEN. 0 _B The WA generation has not yet ended (if it is running and WAGEN has been cleared). 1 _B The WA generation has ended (if it has been running). |
| RSIF | 10 | rwh | Receiver Start Indication Flag 0 _B A receiver start event has not occurred. 1 _B A receiver start event has occurred. |
| DLIF | 11 | rwh | Data Lost Indication Flag 0 _B A data lost event has not occurred. 1 _B A data lost event has occurred. |
| TSIF | 12 | rwh | Transmit Shift Indication Flag 0 _B A transmit shift event has not occurred. 1 _B A transmit shift event has occurred. |
| TBIF | 13 | rwh | Transmit Buffer Indication Flag 0 _B A transmit buffer event has not occurred. 1 _B A transmit buffer event has occurred. |
| RIF | 14 | rwh | Receive Indication Flag 0 _B A receive event has not occurred. 1 _B A receive event has occurred. |
| AIF | 15 | rwh | Alternative Receive Indication Flag 0 _B An alternative receive event has not occurred. 1 _B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0 _B A baud rate generator event has not occurred. 1 _B A baud rate generator event has occurred. |
| 0 | 2, [9:7], [31:17] | r | Reserved Returns 0 if read; not modified in IIS mode. |

1) This status bit can generate a protocol interrupt (see [Page 14-22](#)). The general interrupt status flags are described in the general interrupt chapter.

14.7 Service Request Generation

The USIC module provides 6 service request outputs SR[5:0] to be shared between two channels. The service request outputs SR[5:0] are connected to interrupt nodes in the Nested Vectored Interrupt Controller (NVIC).

Each USIC communication channel can be connected to up to 6 service request handlers (connected to USICx.SR[5:0], though 3 or 4 are normally used, e.g. one for transmission, one for reception, one or two for protocol or error handling, or for the alternative receive events).

14.8 Debug Behaviour

Each USIC communication channel can be pre-configured to enter one of four kernel modes, when the program execution of the CPU is halted by the debugger.

Refer to [Section 14.2.2.2](#) for details.

14.9 Power, Reset and Clock

The USIC module is located in the core power domain. The module can be reset to its default state by a system reset.

The USIC module is clocked by the main clock, MCLK, from SCU. MCLK is disabled by default and can be enabled via the SCU_CGATCLR0 register. Enabling and disabling the module clock could cause a load change and clock blanking could occur as described in the CCU (Clock Gating Control) section of the SCU chapter. It is strongly recommended to set up the module clock in the user initialization code to avoid clock blanking during runtime.

Note: To differentiate from the USIC baud rate generator output, master clock (MCLK), the SCU MCLK is referenced throughout the USIC chapter as f_{PERIPH} .

14.10 Initialization and System Dependencies

The application has to apply the following initialization sequence before operating the USIC module:

- Enable the module by writing 1s to the MODEN and BPMODEN bits in KSCFG register.

14.11 Registers

Table 14-20 shows all registers which are required for programming a USIC channel, as well as the FIFO buffer. It summarizes the USIC communication channel registers and defines the relative addresses and the reset values.

Please note that all registers can be accessed with any access width (8-bit, 16-bit, 32-bit), independent of the described width.

Universal Serial Interface Channel (USIC)

All USIC registers (except bit field KSCFG.SUMCFG) are always reset by a system reset. Bit field KSCFG.SUMCFG is reset by a debug reset.

Note: The register bits marked “w” always deliver 0 when read. They are used to modify flip-flops in other registers or to trigger internal actions.

Figure 14-65 shows the register types of the USIC module registers and channel registers. In a specific microcontroller, module registers of USIC module “x” are marked by the module prefix “USICx_”. Channel registers of USIC module “x” are marked by the channel prefix “USICx_CH0_” and “USICx_CH1_”.

- 1) Details of the module identification registers are described in the implementation section (see [Page 14-158](#)).
- 2) This page shows the general register layout.
- 3) This page shows the register layout in ASC mode.
- 4) This page shows the register layout in SSC mode.
- 5) This page shows the register layout in IIC mode.
- 6) This page shows the register layout in IIS mode.

14.11.1 Address Map

The registers of the USIC communication channel are available at the following base addresses. The exact register address is given by the relative address of the register (given in [Table 14-20](#)) plus the channel base address (given in [Table 14-21](#)).

Table 14-21 Registers Address Space

| Module | Base Address | End Address | Note |
|-----------|-----------------------|-----------------------|------|
| USIC0_CH0 | 48000000 _H | 480001FF _H | — |
| USIC0_CH1 | 48000200 _H | 480003FF _H | — |

Table 14-22 FIFO and Reserved Address Space

| Module | Base Address | End Address | Access Mode | | Note |
|----------|-----------------------|-----------------------|-------------|--|--|
| | | | Read | Write | |
| USIC0 | 48000400 _H | 480007FF _H | nBE | nBE if in direct RAM test mode; otherwise BE | USIC0 RAM area, shared between USIC0_CH0 and USIC0_CH1 |
| reserved | 48000800 _H | 4800FFFF _H | BE | BE | — |

14.11.2 Module Identification Registers

The module identification registers indicate the function and the design step of the USIC modules.

Universal Serial Interface Channel (USIC)

USIC0_ID

Module Identification Register

(4800 0008_H)

Reset Value: 00AA C0XX_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Number MOD_REV defines the revision number. The value of a module revision starts with 01 _H (first revision). |
| MOD_TYPE | [15:8] | r | Module Type This bit field is C0 _H . It defines the module as a 32-bit module. |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines the USIC module identification number (00AA _H = USIC). |

14.11.3 Channel Control and Configuration Registers

14.11.3.1 Channel Control Register

The channel control register contains the enable/disable bits for hardware port control and interrupt generation on channel events, the control of the parity generation and the protocol selection of a USIC channel.

FDR can be written only with a privilege mode access.

Universal Serial Interface Channel (USIC)

CCR

Channel Control Register

| Field | Bits | Type | Description |
|-------------|-------|------|---|
| MODE | [3:0] | rw | <p>Operating Mode</p> <p>This bit field selects the protocol for this USIC channel. Selecting a protocol that is not available (see register CCFG) or a reserved combination disables the USIC channel. When switching between two protocols, the USIC channel has to be disabled before selecting a new protocol. In this case, registers PCR and PSR have to be cleared or updated by software.</p> <p>0_H The USIC channel is disabled. All protocol-related state machines are set to an idle state.</p> <p>1_H The SSC (SPI) protocol is selected.</p> <p>2_H The ASC (SCI, UART) protocol is selected.</p> <p>3_H The IIS protocol is selected.</p> <p>4_H The IIC protocol is selected.</p> <p>Other bit combinations are reserved.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|-------|------|---|
| HPCEN | [7:6] | rw | Hardware Port Control Enable This bit enables the hardware port control for the specified set of DX[3:0] and DOUT[3:0] pins. 00 _B The hardware port control is disabled. 01 _B The hardware port control is enabled for DX0 and DOUT0. 10 _B The hardware port control is enabled for DX3, DX0 and DOUT[1:0]. 11 _B The hardware port control is enabled for DX0, DX[5:3] and DOUT[3:0]. <i>Note: The hardware port control feature is useful only for SSC protocols in half-duplex configurations, such as dual- and quad-SSC. For all other protocols HPCEN must always be written with 00_B.</i> |
| PM | [9:8] | rw | Parity Mode This bit field defines the parity generation of the sampled input values. 00 _B The parity generation is disabled. 01 _B Reserved 10 _B Even parity is selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data). 11 _B Odd parity is selected (parity bit = 0 on odd number of 1s in data, parity bit = 1 on even number of 1s in data). |
| RSIEN | 10 | rw | Receiver Start Interrupt Enable This bit enables the interrupt generation in case of a receiver start event. 0 _B The receiver start interrupt is disabled. 1 _B The receiver start interrupt is enabled. In case of a receiver start event, the service request output SRx indicated by INPR.TBINP is activated. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| DLIEN | 11 | rw | Data Lost Interrupt Enable This bit enables the interrupt generation in case of a data lost event (data received in RBUFx while RDVx = 1). 0 _B The data lost interrupt is disabled. 1 _B The data lost interrupt is enabled. In case of a data lost event, the service request output SRx indicated by INPR.PINP is activated. |
| TSIEN | 12 | rw | Transmit Shift Interrupt Enable This bit enables the interrupt generation in case of a transmit shift event. 0 _B The transmit shift interrupt is disabled. 1 _B The transmit shift interrupt is enabled. In case of a transmit shift interrupt event, the service request output SRx indicated by INPR.TSINP is activated. |
| TBIEN | 13 | rw | Transmit Buffer Interrupt Enable This bit enables the interrupt generation in case of a transmit buffer event. 0 _B The transmit buffer interrupt is disabled. 1 _B The transmit buffer interrupt is enabled. In case of a transmit buffer event, the service request output SRx indicated by INPR.TBINP is activated. |
| RIEN | 14 | rw | Receive Interrupt Enable This bit enables the interrupt generation in case of a receive event. 0 _B The receive interrupt is disabled. 1 _B The receive interrupt is enabled. In case of a receive event, the service request output SRx indicated by INPR.RINP is activated. |
| AIEN | 15 | rw | Alternative Receive Interrupt Enable This bit enables the interrupt generation in case of a alternative receive event. 0 _B The alternative receive interrupt is disabled. 1 _B The alternative receive interrupt is enabled. In case of an alternative receive event, the service request output SRx indicated by INPR.AINP is activated. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|-------------------|------|---|
| BRGIEN | 16 | rw | Baud Rate Generator Interrupt Enable This bit enables the interrupt generation in case of a baud rate generator event. 0 _B The baud rate generator interrupt is disabled. 1 _B The baud rate generator interrupt is enabled. In case of a baud rate generator event, the service request output SRx indicated by INPR.PINP is activated. |
| 0 | [5:4], [31:17] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

14.11.3.2 Channel Configuration Register

The channel configuration register contains indicates the functionality that is available in the USIC channel.

CCFG

Channel Configuration Register

(04_H)

Reset Value: 0000 80CF_H

| | | | | | | | | | | | | | | | |

| 0 | | | | BPS UM | 0 | SUMCFG | | BPN OM | 0 | NOMCFG | | 0 | BPM ODE N | MOD EN | |
| r | | | | w | r | rw | | w | r | rw | | r | w | rw | |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|-------|------|---|
| MODEN | 0 | rw | Module Enable This bit enables the module kernel clock and the module functionality. 0_B The module is switched off immediately (without respecting a stop condition). It does not react on mode control actions and the module clock is switched off. The module does not react on read accesses and ignores write accesses (except to KSCFG). 1_B The module is switched on and can operate. After writing 1 to MODEN, it is recommended to read register KSCFG to avoid pipeline effects in the control block before accessing other USIC registers. |
| BPMODEN | 1 | w | Bit Protection for MODEN This bit enables the write access to the bit MODEN. It always reads 0. 0_B MODEN is not changed. 1_B MODEN is updated with the written value. |
| NOMCFG | [5:4] | rw | Normal Operation Mode Configuration This bit field defines the kernel mode applied in normal operation mode. 00_B Run mode 0 is selected. 01_B Run mode 1 is selected. 10_B Stop mode 0 is selected. 11_B Stop mode 1 is selected. |
| BPNOM | 7 | w | Bit Protection for NOMCFG This bit enables the write access to the bit field NOMCFG. It always reads 0. 0_B NOMCFG is not changed. 1_B NOMCFG is updated with the written value. |
| SUMCFG | [9:8] | rw | Suspend Mode Configuration This bit field defines the kernel mode applied in suspend mode. Coding like NOMCFG. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|-----------------------------|------|--|
| BPSUM | 11 | w | Bit Protection for SUMCFG This bit enables the write access to the bit field SUMCFG. It always reads 0. 0 _B SUMCFG is not changed. 1 _B SUMCFG is updated with the written value. |
| 0 | [3:2], 6, 10, [31:12] | r | Reserved Read as 0; should be written with 0. Bit 2 can read as 1 after BootROM exit (but can be ignored). |

Universal Serial Interface Channel (USIC)

14.11.3.4 Interrupt Node Pointer Register

The interrupt node pointer register defines the service request output SRx that is activated if the corresponding event occurs and interrupt generation is enabled.

INPR

Interrupt Node Pointer Register (18_H) **Reset Value: 0000 0000_H**

| | | | | | | | | | | | | | | | |
|----|------|----|----|------|----|----|-------|----|----|-------|----|----|------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | PINP | | |
| r | | | | | | | | | | | | | rw | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Field | Bits | Type | Description |
|-------|--------|------|--|
| TSINP | [2:0] | rw | Transmit Shift Interrupt Node Pointer This bit field defines which service request output SRx becomes activated in case of a transmit shift interrupt. 000 _B Output SR0 becomes activated. 001 _B Output SR1 becomes activated. 010 _B Output SR2 becomes activated. 011 _B Output SR3 becomes activated. 100 _B Output SR4 becomes activated. 101 _B Output SR5 becomes activated. <i>Note: All other settings of the bit field are reserved.</i> |
| TBINP | [6:4] | rw | Transmit Buffer Interrupt Node Pointer This bit field defines which service request output SRx will be activated in case of a transmit buffer interrupt or a receive start interrupt. Coding like TSINP. |
| RINP | [10:8] | rw | Receive Interrupt Node Pointer This bit field defines which service request output SRx will be activated in case of a receive interrupt. Coding like TSINP. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|-----------------------|------|--|
| AINP | [14:12] | rw | Alternative Receive Interrupt Node Pointer This bit field defines which service request output SRx will be activated in case of a alternative receive interrupt. Coding like TSINP. |
| PINP | [18:16] | rw | Protocol Interrupt Node Pointer This bit field defines which service request output SRx becomes activated in case of a protocol interrupt. Coding like TSINP. |
| 0 | 3, 7, 11, 15, [31:19] | r | Reserved Read as 0; should be written with 0. |

14.11.4 Protocol Related Registers

14.11.4.1 Protocol Control Registers

The bits in the protocol control register define protocol-specific functions. They have to be configured by software before enabling a new protocol. Only the bits used for the selected protocol are taken into account, whereas the other bit positions always read as 0. The protocol-specific meaning is described in the related protocol section.

PCR

Protocol Control Register (3C_H) **Reset Value: 0000 0000_H**

| CTR_x (x = 0-31) | x | rw | Protocol Control Bit x This bit is a protocol control bit. |

Universal Serial Interface Channel (USIC)

14.11.4.2 Protocol Status Register

The flags in the protocol status register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. These flags should be cleared by software before enabling a new protocol. The protocol-specific meaning is described in the related protocol section.

14.11.5 Input Stage Register

14.11.5.1 Input Control Registers

The input control registers contain the bits to define the characteristics of the input stages (input stage DX0 is controlled by register DX0CR, etc.).

Universal Serial Interface Channel (USIC)

DX0CR

Input Control Register 0 (1C_H) **Reset Value: 0000 0000_H**

DX2CR

Input Control Register 2 (24_H) **Reset Value: 0000 0000_H**

DX3CR

Input Control Register 3 (28_H) **Reset Value: 0000 0000_H**

DX4CR

Input Control Register 4 (2C_H) **Reset Value: 0000 0000_H**

DX5CR

Input Control Register 5 (30_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|-------|------|--|
| DSEL | [2:0] | rw | Data Selection for Input Signal This bit field defines the input data signal for the corresponding input line for protocol pre-processor. The selection can be made from the input vector DXn[G:A]. 000 _B The data input DXnA is selected. 001 _B The data input DXnB is selected. 010 _B The data input DXnC is selected. 011 _B The data input DXnD is selected. 100 _B The data input DXnE is selected. 101 _B The data input DXnF is selected. 110 _B The data input DXnG is selected. 111 _B The data input is always 1. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| INSW | 4 | rw | Input Switch This bit defines if the data shift unit input is derived from the input data path DXn or from the selected protocol pre-processors. 0_B The input of the data shift unit is controlled by the protocol pre-processor. 1_B The input of the data shift unit is connected to the selected data input line. This setting is used if the signals are directly derived from an input pin without treatment by the protocol pre-processor. |
| DFEN | 5 | rw | Digital Filter Enable This bit enables/disables the digital filter for signal DXnS. 0_B The input signal is not digitally filtered. 1_B The input signal is digitally filtered. |
| DSEN | 6 | rw | Data Synchronization Enable This bit selects if the asynchronous input signal or the synchronized (and optionally filtered) signal DXnS can be used as input for the data shift unit. 0_B The un-synchronized signal can be taken as input for the data shift unit. 1_B The synchronized signal can be taken as input for the data shift unit. |
| DPOL | 8 | rw | Data Polarity for DXn This bit defines the signal polarity of the input signal. 0_B The input signal is not inverted. 1_B The input signal is inverted. |
| SFSEL | 9 | rw | Sampling Frequency Selection This bit defines the sampling frequency of the digital filter for the synchronized signal DXnS. 0_B The sampling frequency is f_{PERIPH} . 1_B The sampling frequency is f_{FD} . |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|------------|------------------------|------|---|
| CM | [11:10] | rw | Combination Mode This bit field selects which edge of the synchronized (and optionally filtered) signal DXnS activates the trigger output DXnT of the input stage. 00 _B The trigger activation is disabled. 01 _B A rising edge activates DXnT. 10 _B A falling edge activates DXnT. 11 _B Both edges activate DXnT. |
| DXS | 15 | rh | Synchronized Data Value This bit indicates the value of the synchronized (and optionally filtered) input signal. 0 _B The current value of DXnS is 0. 1 _B The current value of DXnS is 1. |
| 0 | 3, 7, [14:12], [31:16] | r | Reserved Read as 0; should be written with 0. |

| 0 | DCTQ | | | | | PCTQ | | CTQSEL | | 0 | PPPEN | TMEN | 0 | CLKSEL | |
| r | rw | | | | | rw | | rw | | r | rw | rw | r | rw | |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|-------|------|--|
| CLKSEL | [1:0] | rw | Clock Selection This bit field defines the input frequency f_{PIN} 00_B The fractional divider frequency f_{FD} is selected. 01_B Reserved, no action 10_B The trigger signal DX1T defines f_{PIN} . Signal MCLK toggles with f_{PIN} . 11_B Signal MCLK corresponds to the DX1S signal and the frequency f_{PIN} is derived from the rising edges of DX1S. |
| TMEN | 3 | rw | Timing Measurement Enable This bit enables the timing measurement of the capture mode timer. 0_B Timing measurement is disabled: The trigger signals DX0T and DX1T are ignored. 1_B Timing measurement is enabled: The 10-bit counter is incremented by 1 with f_{PPP} and stops counting when reaching its maximum value. If one of the trigger signals DX0T or DX1T become active, the counter value is captured into bit field CTV, the counter is cleared and a transmit shift event is generated. |
| PPPEN | 4 | rw | Enable 2:1 Divider for f_{PPP} This bit defines the input frequency f_{PPP} . 0_B The 2:1 divider for f_{PPP} is disabled. $f_{PPP} = f_{PIN}$ 1_B The 2:1 divider for f_{PPP} is enabled. $f_{PPP} = f_{MCLK} = f_{PIN} / 2$. |
| CTQSEL | [7:6] | rw | Input Selection for CTQ This bit defines the length of a time quantum for the protocol pre-processor. 00_B $f_{CTQIN} = f_{PDIV}$ 01_B $f_{CTQIN} = f_{PPP}$ 10_B $f_{CTQIN} = f_{SCLK}$ 11_B $f_{CTQIN} = f_{MCLK}$ |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-----------------|-------------------|------|--|
| PCTQ | [9:8] | rw | Pre-Divider for Time Quanta Counter This bit field defines length of a time quantum t_q for the time quanta counter in the protocol pre-processor. $t_q = (PCTQ + 1) / f_{CTQIN}$ |
| DCTQ | [14:10] | rw | Denominator for Time Quanta Counter This bit field defines the number of time quanta t_q taken into account by the time quanta counter in the protocol pre-processor. |
| PDIV | [25:16] | rw | Divider Mode: Divider Factor to Generate f_{PDIV} This bit field defines the ratio between the input frequency f_{PPP} and the divider frequency f_{PDIV} . |
| SCLKOSEL | 28 | rw | Shift Clock Output Select This bit field selects the input source for the SCLKOUT signal. 0_B SCLK from the baud rate generator is selected as the SCLKOUT input source. 1_B The transmit shift clock from DX1 input stage is selected as the SCLKOUT input source. <i>Note: The setting SCLKOSEL = 1 is used only when complete closed loop delay compensation is required for a slave SSC/IIS. The default setting of SCLKOSEL = 0 should be always used for all other cases.</i> |
| MCLKCFG | 29 | rw | Master Clock Configuration This bit field defines the level of the passive phase of the MCLKOUT signal. 0_B The passive level is 0. 1_B The passive level is 1. |
| SCLKCFG | [31:30] | rw | Shift Clock Output Configuration This bit field defines the level of the passive phase of the SCLKOUT signal and enables/disables a delay of half of a SCLK period. 00_B The passive level is 0 and the delay is disabled. 01_B The passive level is 1 and the delay is disabled. 10_B The passive level is 0 and the delay is enabled. 11_B The passive level is 1 and the delay is enabled. |
| 0 | 2, 5, 15, [27:26] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

14.11.6.3 Capture Mode Timer Register

The captured timer value is provided by the register CMTR.

CMTR

Capture Mode Timer Register

(44_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| CTV | [9:0] | rwh | Captured Timer Value The value of the counter is captured into this bit field if one of the trigger signals DX0T or DX1T are activated by the corresponding input stage. |
| 0 | [31:10] | r | Reserved Read as 0; should be written with 0. |

14.11.7 Transfer Control and Status Registers

14.11.7.1 Shift Control Register

The data shift unit is controlled by the register SCTR. The values in this register are applied for data transmission and reception.

Please note that the shift control settings SDIR, WLE, FLE, DSM and HPCDIR are shared between transmitter and receiver. They are internally “frozen” for a each data word transfer in the transmitter with the first transmit shift clock edge and with the first receive shift clock edge in the receiver. The software has to take care that updates of these bit fields by software are done coherently (e.g. refer to the receiver start event indication PSR.RSIF).

Universal Serial Interface Channel (USIC)

| r | | | | | | rw | | rw | | r | rw | rw | | rw | rw |

| Field | Bits | Type | Description |
|-------------|------|------|--|
| SDIR | 0 | rw | Shift Direction This bit defines the shift direction of the data words for transmission and reception. 0 _B Shift LSB first. The first data bit of a data word is located at bit position 0. 1 _B Shift MSB first. The first data bit of a data word is located at the bit position given by bit field SCTR.WLE. |
| PDL | 1 | rw | Passive Data Level This bit defines the output level at the shift data output signal when no data is available for transmission. The PDL level is output with the first relevant transmit shift clock edge of a data word. 0 _B The passive data level is 0. 1 _B The passive data level is 1. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|-------|------|--|
| DSM | [3:2] | rw | Data Shift Mode This bit field describes how the receive and transmit data is shifted in and out. 00 _B Receive and transmit data is shifted in and out one bit at a time through DX0 and DOUT0. 01 _B Reserved. 10 _B Receive and transmit data is shifted in and out two bits at a time through two input stages (DX0 and DX3) and DOUT[1:0] respectively. 11 _B Receive and transmit data is shifted in and out four bits at a time through four input stages (DX0, DX[5:3]) and DOUT[3:0] respectively. <i>Note: Dual- and Quad-output modes are used only by the SSC protocol. For all other protocols DSM must always be written with 00_B.</i> |
| HPCDIR | 4 | rw | Port Control Direction This bit defines the direction of the port pin(s) which allows hardware pin control (CCR.PCEN = 1). 0 _B The pin(s) with hardware pin control enabled are selected to be in input mode. 1 _B The pin(s) with hardware pin control enabled are selected to be in output mode. |
| DOCFG | [7:6] | rw | Data Output Configuration This bit defines the relation between the internal shift data value and the data output signal DOUTx. X0 _B DOUTx = shift data value X1 _B DOUTx = inverted shift data value |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|------------|---------|------|--|
| TRM | [9:8] | rw | Transmission Mode This bit field describes how the shift control signal is interpreted by the DSU. Data transfers are only possible while the shift control signal is active. 00 _B The shift control signal is considered as inactive and data frame transfers are not possible. 01 _B The shift control signal is considered active if it is at 1-level. This is the setting to be programmed to allow data transfers. 10 _B The shift control signal is considered active if it is at 0-level. It is recommended to avoid this setting and to use the inversion in the DX2 stage in case of a low-active signal. 11 _B The shift control signal is considered active without referring to the actual signal level. Data frame transfer is possible after each edge of the signal. |
| FLE | [21:16] | rwh | Frame Length This bit field defines how many bits are transferred within a data frame. A data frame can consist of several concatenated data words. If TCSR.FLEMD = 1, the value can be updated automatically by the data handler. |
| WLE | [27:24] | rwh | Word Length This bit field defines the data word length (amount of bits that are transferred in each data word) for reception and transmission. The data word is always right-aligned in the data buffer at the bit positions [WLE down to 0]. If TCSR.WLEMD = 1, the value can be updated automatically by the data handler. 0 _H The data word contains 1 data bit located at bit position 0. 1 _H The data word contains 2 data bits located at bit positions [1:0]. ... E _H The data word contains 15 data bits located at bit positions [14:0]. F _H The data word contains 16 data bits located at bit positions [15:0]. |

Universal Serial Interface Channel (USIC)

| SELMD | 1 | rw | <p>Select Mode</p> <p>This bit can be used mainly for the SSC protocol. It enables the data handler to automatically update bit field PCR.CTR[20:16] by the transmit control information TCI[4:0] and clear bit field PCR.CTR[23:21] (see Page 14-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of PCR.CTR[23:16] is disabled.</p> <p>1_B The automatic update of PCR.CTR[23:16] is disabled.</p> |
| FLEMD | 2 | rw | <p>FLE Mode</p> <p>This bit enables the data handler to automatically update bits SCTR.FLE[4:0] by the transmit control information TCI[4:0] and to clear bit SCTR.FLE[5] (see Page 14-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of FLE is disabled.</p> <p>1_B The automatic update of FLE is enabled.</p> |
| WAMD | 3 | rw | <p>WA Mode</p> <p>This bit can be used mainly for the IIS protocol. It enables the data handler to automatically update bit TCSR.WA by the transmit control information TCI[4] (see Page 14-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of bit WA is disabled.</p> <p>1_B The automatic update of bit WA is enabled.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| HPCMD | 4 | rw | <p>Hardware Port Control Mode</p> <p>This bit can be used mainly for the dual and quad SSC protocol. It enables the data handler to automatically update bit SCTR.DSM by the transmit control information TCI[1:0] and bit SCTR.HPCDIR by TCI[2] (see Page 14-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of bits SCTR.DSM and SCTR.HPCDIR is disabled.</p> <p>1_B The automatic update of bits SCTR.DSM and SCTR.HPCDIR is enabled.</p> |
| SOF | 5 | rwh | <p>Start Of Frame</p> <p>This bit is only taken into account for the SSC protocol, otherwise it is ignored. It indicates that the data word in TBUF is considered as the first word of a new SSC frame if it is valid for transmission (TCSR.TDV = 1). This bit becomes cleared when the TBUF data word is transferred to the transmit shift register.</p> <p>0_B The data word in TBUF is not considered as first word of a frame.</p> <p>1_B The data word in TBUF is considered as first word of a frame. A currently running frame is finished and MSLS becomes deactivated (respecting the programmed delays).</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------|------|------|--|
| EOF | 6 | rwh | <p>End Of Frame</p> <p>This bit is only taken into account for the SSC protocol, otherwise it is ignored. It can be modified automatically by the data handler if bit WLEMD = 1. It indicates that the data word in TBUF is considered as the last word of an SSC frame. If it is the last word, the MSLS signal becomes inactive after the transfer, respecting the programmed delays. This bit becomes cleared when the TBUF data word is transferred to the transmit shift register.</p> <p>0_B The data word in TBUF is not considered as last word of an SSC frame.</p> <p>1_B The data word in TBUF is considered as last word of an SSC frame.</p> |
| TDV | 7 | rh | <p>Transmit Data Valid</p> <p>This bit indicates that the data word in the transmit buffer TBUF can be considered as valid for transmission. The TBUF data word can only be sent out if TDV = 1. It is automatically set when data is moved to TBUF (by writing to one of the transmit buffer input locations TBUFx, or optionally, by the bypass or FIFO mechanism).</p> <p>0_B The data word in TBUF is not valid for transmission.</p> <p>1_B The data word in TBUF is valid for transmission and a transmission start is possible. New data should not be written to a TBUFx input location while TDV = 1.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| TDSSM | 8 | rw | TBUF Data Single Shot Mode This bit defines if the data word TBUF data is considered as permanently valid or if the data should only be transferred once. 0 _B The data word in TBUF is not considered as invalid after it has been loaded into the transmit shift register. The loading of the TBUF data into the shift register does not clear TDV. 1 _B The data word in TBUF is considered as invalid after it has been loaded into the shift register. In ASC and IIC mode, TDV is cleared with the TBI event, whereas in SSC and IIS mode, it is cleared with the RSI event. TDSSM = 1 has to be programmed if an optional data buffer is used. |
| TDEN | [11:10] | rw | TBUF Data Enable This bit field controls the gating of the transmission start of the data word in the transmit buffer TBUF. 00 _B A transmission start of the data word in TBUF is disabled. If a transmission is started, the passive data level is sent out. 01 _B A transmission of the data word in TBUF can be started if TDV = 1. 10 _B A transmission of the data word in TBUF can be started if TDV = 1 while DX2S = 0. 11 _B A transmission of the data word in TBUF can be started if TDV = 1 while DX2S = 1. |
| TDVTR | 12 | rw | TBUF Data Valid Trigger This bit enables the transfer trigger unit to set bit TCSR.TE if the trigger signal DX2T becomes active for event driven transfer starts, e.g. timer-based or depending on an event at an input pin. Bit TDVTR has to be 0 for protocols where the input stage DX2 is used for data shifting. 0 _B Bit TCSR.TE is permanently set. 1 _B Bit TCSR.TE is set if DX2T becomes active while TDV = 1. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|------|------|--|
| WA | 13 | rwh | <p>Word Address</p> <p>This bit is only taken into account for the IIS protocol, otherwise it is ignored. It can be modified automatically by the data handler if bit WAMD = 1. Bit WA defines for which channel the data stored in TBUF will be transmitted.</p> <p>0_B The data word in TBUF will be transmitted after a falling edge of WA has been detected (referring to PSR.WA).</p> <p>1_B The data word in TBUF will be transmitted after a rising edge of WA has been detected (referring to PSR.WA).</p> |
| TSOF | 24 | rh | <p>Transmitted Start Of Frame</p> <p>This bit indicates if the latest start of a data word transmission has taken place for the first data word of a new data frame. This bit is updated with the transmission start of each data word.</p> <p>0_B The latest data word transmission has not been started for the first word of a data frame.</p> <p>1_B The latest data word transmission has been started for the first word of a data frame.</p> |
| TV | 26 | rh | <p>Transmission Valid</p> <p>This bit represents the transmit buffer underflow and indicates if the latest start of a data word transmission has taken place with a valid data word from the transmit buffer TBUF. This bit is updated with the transmission start of each data word.</p> <p>0_B The latest start of a data word transmission has taken place while no valid data was available. As a result, the transmission of a data words with passive level (SCTR.PDL) has been started.</p> <p>1_B The latest start of a data word transmission has taken place with valid data from TBUF.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|------------|-------------------------|------|---|
| TVC | 27 | rh | Transmission Valid Cumulated This bit cumulates the transmit buffer underflow indication TV. It is cleared automatically together with bit TV and has to be set by writing FMR.ATVC = 1. 0_B Since TVC has been set, at least one data buffer underflow condition has occurred. 1_B Since TVC has been set, no data buffer underflow condition has occurred. |
| TE | 28 | rh | Trigger Event If the transfer trigger mechanism is enabled, this bit indicates that a trigger event has been detected (DX2T = 1) while TCSR.TDV = 1. If the event trigger mechanism is disabled, the bit TE is permanently set. It is cleared by writing FMR.MTDV = 10_B or when the data word located in TBUF is loaded into the shift register. 0_B The trigger event has not yet been detected. A transmission of the data word in TBUF can not be started. 1_B The trigger event has been detected (or the trigger mechanism is switched off) and a transmission of the data word in TBUF can be started. |
| 0 | 9, [23:14], 25, [31:29] | r | Reserved Read as 0; should be written with 0. |

14.11.7.3 Flag Modification Registers

The flag modification register FMR allows the modification of control and status flags related to data handling by using only write accesses. Read accesses to FMR always deliver 0 at all bit positions.

Additionally, the service request outputs of this USIC channel can be activated by software (the activation is triggered by the write access and is deactivated automatically).

Universal Serial Interface Channel (USIC)

FMR

Flag Modification Register

| Field | Bits | Type | Description |
|-------|-------|------|---|
| MTDV | [1:0] | w | Modify Transmit Data Valid Writing to this bit field can modify bits TCSR.TDV and TCSR.TE to control the start of a data word transmission by software. 00 _B No action. 01 _B Bit TDV is set, TE is unchanged. 10 _B Bits TDV and TE are cleared. 11 _B Reserved |
| ATVC | 4 | w | Activate Bit TVC Writing to this bit can set bit TCSR.TVC to start a new cumulation of the transmit buffer underflow condition. 0 _B No action. 1 _B Bit TCSR.TVC is set. |
| CRDV0 | 14 | w | Clear Bits RDV for RBUF0 Writing 1 to this bit clears bits RBUF01SR.RDV00 and RBUF01SR.RDV10 to declare the received data in RBUF0 as no longer valid (to emulate a read action). 0 _B No action. 1 _B Bits RBUF01SR.RDV00 and RBUF01SR.RDV10 are cleared. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---|------------------------|------|---|
| CRDV1 | 15 | w | Clear Bit RDV for RBUF1 Writing 1 to this bit clears bits RBUF01SR.RDV01 and RBUF01SR.RDV11 to declare the received data in RBUF1 as no longer valid (to emulate a read action). 0 _B No action. 1 _B Bits RBUF01SR.RDV01 and RBUF01SR.RDV11 are cleared. |
| SIO0, SIO1, SIO2, SIO3, SIO4, SIO5 | 16, 17, 18, 19, 20, 21 | w | Set Interrupt Output SRx Writing a 1 to this bit field activates the service request output SRx of this USIC channel. It has no impact on service request outputs of other USIC channels. 0 _B No action. 1 _B The service request output SRx is activated. |
| 0 | [3:2], [13:5], [31:22] | r | Reserved Read as 0; should be written with 0. |

14.11.8 Data Buffer Registers

14.11.8.1 Transmit Buffer Locations

The 32 independent data input locations TBUF00 to TBUF31 are address locations that can be used as data entry locations for the transmit buffer. Data written to one of these locations will appear in a common register TBUF. Additionally, the 5 bit coding of the number [31:0] of the addressed data input location represents the transmit control information TCI (please refer to the protocol sections for more details).

The internal transmit buffer register TBUF contains the data that will be loaded to the transmit shift register for the next transmission of a data word. It can be read out at all TBUF00 to TBUF31 addresses.

Universal Serial Interface Channel (USIC)

TBUF_x (x = 00-31)

Transmit Buffer Input Location x ($80_H + x \cdot 4$) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|---------|------|---|
| TDATA | [15:0] | rwh | Transmit Data This bit field contains the data to be transmitted (read view). A data write action to at least the low byte of TDATA sets TCSR.TDV. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

14.11.8.2 Receive Buffer Registers RBUF0, RBUF1

The receive buffer register RBUF0 contains the data received from RSR0[3:0]. A read action does not change the status of the receive data from “not yet read = valid” to “already read = not valid”.

RBUF0

Receiver Buffer Register 0 ($5C_H$) **Reset Value: 0000 0000_H**

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| DSR0 | [15:0] | rh | Data of Shift Registers 0[3:0] |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

The receive buffer register RBUF1 contains the data received from RSR1[3:0]. A read action does not change the status of the receive data from “not yet read = valid” to “already read = not valid”.

RBUF1

Receiver Buffer Register 1

(60_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |

| Field | Bits | Type | Description |
|--------------|-------|------|---|
| WLEN0 | [3:0] | rh | Received Data Word Length in RBUF0 This bit field indicates how many bits have been received within the last data word stored in RBUF0. This number indicates how many data bits have to be considered as receive data, whereas the other bits in RBUF0 have been cleared automatically. The received bits are always right-aligned. For all protocol modes besides dual and quad SSC, Received data word length = WLEN0 + 1 For dual SSC mode, Received data word length = WLEN0 + 2 For quad SSC mode, Received data word length = WLEN0 + 4 |
| SOF0 | 6 | rh | Start of Frame in RBUF0 This bit indicates whether the data word in RBUF0 has been the first data word of a data frame. 0 _B The data in RBUF0 has not been the first data word of a data frame. 1 _B The data in RBUF0 has been the first data word of a data frame. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| PAR0 | 8 | rh | Protocol-Related Argument in RBUF0 This bit indicates the value of the protocol-related argument. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF0. The meaning of this bit is described in the corresponding protocol chapter. |
| PERR0 | 9 | rh | Protocol-related Error in RBUF0 This bit indicates if the value of the protocol-related argument meets an expected value. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF0. The meaning of this bit is described in the corresponding protocol chapter. 0_B The received protocol-related argument PAR matches the expected value. The reception of the data word sets bit PSR.RIF and can generate a receive interrupt. 1_B The received protocol-related argument PAR does not match the expected value. The reception of the data word sets bit PSR.AIF and can generate an alternative receive interrupt. |
| RDV00 | 13 | rh | Receive Data Valid in RBUF0 This bit indicates the status of the data content of register RBUF0. This bit is identical to bit RBUF01SR.RDV10 and allows consisting reading of information for the receive buffer registers. It is set when a new data word is stored in RBUF0 and automatically cleared if it is read out via RBUF. 0_B Register RBUF0 does not contain data that has not yet been read out. 1_B Register RBUF0 contains data that has not yet been read out. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| RDV01 | 14 | rh | Receive Data Valid in RBUF1 This bit indicates the status of the data content of register RBUF1. This bit is identical to bit RBUF01SR.RDV11 and allows consisting reading of information for the receive buffer registers. It is set when a new data word is stored in RBUF1 and automatically cleared if it is read out via RBUF. 0 _B Register RBUF1 does not contain data that has not yet been read out. 1 _B Register RBUF1 contains data that has not yet been read out. |
| DS0 | 15 | rh | Data Source This bit indicates which receive buffer register (RBUF0 or RBUF1) is currently visible in registers RBUF(D) and in RBUF0SR for the associated status information. It indicates which buffer contains the oldest data (the data that has been received first). This bit is identical to bit RBUF01SR.DS1 and allows consisting reading of information for the receive buffer registers. 0 _B The register RBUF contains the data of RBUF0 (same for associated status information). 1 _B The register RBUF contains the data of RBUF1 (same for associated status information). |
| WLEN1 | [19:16] | rh | Received Data Word Length in RBUF1 This bit field indicates how many bits have been received within the last data word stored in RBUF1. This number indicates how many data bits have to be considered as receive data, whereas the other bits in RBUF1 have been cleared automatically. The received bits are always right-aligned. For all protocol modes besides dual and quad SSC, Received data word length = WLEN1 + 1 For dual SSC mode, Received data word length = WLEN1 + 2 For quad SSC mode, Received data word length = WLEN1 + 4 |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| SOF1 | 22 | rh | Start of Frame in RBUF1 This bit indicates whether the data word in RBUF1 has been the first data word of a data frame. 0 _B The data in RBUF1 has not been the first data word of a data frame. 1 _B The data in RBUF1 has been the first data word of a data frame. |
| PAR1 | 24 | rh | Protocol-Related Argument in RBUF1 This bit indicates the value of the protocol-related argument. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF1. The meaning of this bit is described in the corresponding protocol chapter. |
| PERR1 | 25 | rh | Protocol-related Error in RBUF1 This bit indicates if the value of the protocol-related argument meets an expected value. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF1. The meaning of this bit is described in the corresponding protocol chapter. 0 _B The received protocol-related argument PAR matches the expected value. The reception of the data word sets bit PSR.RIF and can generate a receive interrupt. 1 _B The received protocol-related argument PAR does not match the expected value. The reception of the data word sets bit PSR.AIF and can generate an alternative receive interrupt. |
| RDV10 | 29 | rh | Receive Data Valid in RBUF0 This bit indicates the status of the data content of register RBUF0. This bit is identical to bit RBUF01SR.RDV00 and allows consistent reading of information for the receive buffer registers. 0 _B Register RBUF0 does not contain data that has not yet been read out. 1 _B Register RBUF0 contains data that has not yet been read out. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---|------|--|
| RDV11 | 30 | rh | Receive Data Valid in RBUF1 This bit indicates the status of the data content of register RBUF1. This bit is identical to bit RBUF01SR.RDV01 and allows consisting reading of information for the receive buffer registers. 0 _B Register RBUF1 does not contain data that has not yet been read out. 1 _B Register RBUF1 contains data that has not yet been read out. |
| DS1 | 31 | rh | Data Source This bit indicates which receive buffer register (RBUF0 or RBUF1) is currently visible in registers RBUF(D) and in RBUF SR for the associated status information. It indicates which buffer contains the oldest data (the data that has been received first). This bit is identical to bit RBUF01SR.DS0 and allows consisting reading of information for the receive buffer registers. 0 _B The register RBUF contains the data of RBUF0 (same for associated status information). 1 _B The register RBUF contains the data of RBUF1 (same for associated status information). |
| 0 | [5:4], 7, [12:10], [21:20], 23, [28:26] | r | Reserved Read as 0; should be written with 0. |

14.11.8.3 Receive Buffer Registers RBUF, RBUFD, RBUFSR

The receiver buffer register RBUF shows the content of the either RBUF0 or RBUF1, depending on the order of reception. Always the oldest data (the data word that has been received first) from both receive buffers can be read from RBUF. It is recommended to read out the received data from RBUF instead of RBUF0/1. With a read access of at least the low byte of RBUF, the status of the receive data is automatically changed from “not yet read = valid” to “already read = not valid”, the content of RBUF becomes updated, and the next received data word becomes visible in RBUF.

Universal Serial Interface Channel (USIC)

RBUF

Receiver Buffer Register

(54_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| DSR | [15:0] | rh | Received Data This bit field monitors the content of either RBUF0 or RBUF1, depending on the reception sequence. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

If a debugger should be used to monitor the received data, the automatic update mechanism has to be de-activated to guaranty data consistency. Therefore, the receiver buffer register for debugging RBUFD is available. It is similar to RBUF, but without the automatic update mechanism by a read action. So a debugger (or other monitoring function) can read RBUFD without disturbing the receive sequence.

RBUFD

Receiver Buffer Register for Debugger(58_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| DSR | [15:0] | rh | Data from Shift Register Same as RBUF.DSR, but without releasing the buffer after a read action. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

The receive buffer status register RBUF01SR provides the status of the data in receive buffers RBUF and RBUFD. If bits RBUF01SR.DS0 (or RBUF01SR.DS1) are 0, the lower 16-bit content of RBUF01SR is monitored in RBUF01SR, otherwise the upper 16-bit content of RBUF01SR is shown.

| BDV | 0 | BPRI | BDV | BDEN | 0 | BDS | SM | 0 | | | | BWLE | | | |
| rh | r | rw | rw | rw | r | rw | | r | | | | rw | | | |

| Field | Bits | Type | Description |
|--------------|-------|------|--|
| BWLE | [3:0] | rw | Bypass Word Length This bit field defines the word length of the bypass data. The word length is given by BWLE + 1 with the data word being right-aligned in the data buffer at the bit positions [BWLE down to 0]. The bypass data word is always considered as an own frame with the length of BWLE. Same coding as SCTR.WLE. |
| BDSSM | 8 | rw | Bypass Data Single Shot Mode This bit defines if the bypass data is considered as permanently valid or if the bypass data is only transferred once (single shot mode). 0 _B The bypass data is still considered as valid after it has been loaded into TBUF. The loading of the data into TBUF does not clear BDV. 1 _B The bypass data is considered as invalid after it has been loaded into TBUF. The loading of the data into TBUF clears BDV. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| BDEN | [11:10] | rw | Bypass Data Enable This bit field defines if and how the transfer of bypass data to TBUF is enabled. 00 _B The transfer of bypass data is disabled. 01 _B The transfer of bypass data to TBUF is possible. Bypass data will be transferred to TBUF according to its priority if BDV = 1. 10 _B Gated bypass data transfer is enabled. Bypass data will be transferred to TBUF according to its priority if BDV = 1 and while DX2S = 0. 11 _B Gated bypass data transfer is enabled. Bypass data will be transferred to TBUF according to its priority if BDV = 1 and while DX2S = 1. |
| BDVTR | 12 | rw | Bypass Data Valid Trigger This bit enables the bypass data for being tagged valid when DX2T is active (for time framing or time-out purposes). 0 _B Bit BDV is not influenced by DX2T. 1 _B Bit BDV is set if DX2T is active. |
| BPRIO | 13 | rw | Bypass Priority This bit defines the priority between the bypass data and the transmit FIFO data. 0 _B The transmit FIFO data has a higher priority than the bypass data. 1 _B The bypass data has a higher priority than the transmit FIFO data. |
| BDV | 15 | rh | Bypass Data Valid This bit defines if the bypass data is valid for a transfer to TBUF. This bit is set automatically by a write access to at least the low-byte of register BYP. It can be cleared by software by writing TRBSCR.CBDV. 0 _B The bypass data is not valid. 1 _B The bypass data is valid. |
| BSELO | [20:16] | rw | Bypass Select Outputs This bit field contains the value that is written to PCR.CTR[20:16] if bypass data is transferred to TBUF while TCSR.SELMD = 1. In the SSC protocol, this bit field can be used to define which SELOx output line will be activated when bypass data is transmitted. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|-----------------------|------|--|
| BHPC | [23:21] | rw | Bypass Hardware Port Control This bit field contains the value that is written to SCTR[4:2] if bypass data is transferred to TBUF while TCSR.HPCMD = 1. In the SSC protocol, this bit field can be used to define the data shift mode and if hardware port control is enabled through CCR.HPCEN = 1, the pin direction when bypass data is transmitted. |
| 0 | [7:4], 9, 14, [31:24] | r | Reserved Read as 0; should be written with 0. |

14.11.9.2 General FIFO Buffer Control Registers

The transmit and receive FIFO status information of USICx_CHy is given in registers USICx_CHy.TRBSR.

The bits related to the transmitter buffer in this register can only be written if the transmit buffer functionality is enabled by CCFG.TB = 1, otherwise write accesses are ignored. A similar behavior applies for the bits related to the receive buffer referring to CCFG.RB = 1.

The interrupt flags (event flags) in the transmit and receive FIFO status register TRBSR can be cleared by writing a 1 to the corresponding bit position in register TRBSCR, whereas writing a 0 has no effect on these bits. Writing a 1 by software to SRBI, RBERI, ARBI, STBI, or TBERI sets the corresponding bit to simulate the detection of a transmit/receive buffer event, but without activating any service request output (therefore, see FMR.SIOx).

Bits TBUS and RBUS have been implemented for testing purposes. They can be ignored by data handling software. Please note that a read action can deliver either a 0 or a 1 for these bits. It is recommended to treat them as "don't care".

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------|------|------|--|
| SRBI | 0 | rwh | Standard Receive Buffer Event This bit indicates that a standard receive buffer event has been detected. It is cleared by writing TRBSCR.CSRBI = 1. If enabled by RBCTR.SRBIEN, the service request output SRx selected by RBCTR.SRBINP becomes activated if a standard receive buffer event is detected. 0 _B A standard receive buffer event has not been detected. 1 _B A standard receive buffer event has been detected. |
| RBERI | 1 | rwh | Receive Buffer Error Event This bit indicates that a receive buffer error event has been detected. It is cleared by writing TRBSCR.CRBERI = 1. If enabled by RBCTR.RBERIEN, the service request output SRx selected by RBCTR.ARBINP becomes activated if a receive buffer error event is detected. 0 _B A receive buffer error event has not been detected. 1 _B A receive buffer error event has been detected. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| ARBI | 2 | rwh | Alternative Receive Buffer Event This bit indicates that an alternative receive buffer event has been detected. It is cleared by writing $TRBSCR.CARBI = 1$. If enabled by $RBCTR.ARBIE$, the service request output SRx selected by $RBCTR.ARBINP$ becomes activated if an alternative receive buffer event is detected. 0_B An alternative receive buffer event has not been detected. 1_B An alternative receive buffer event has been detected. |
| EMPTY | 3 | rh | Receive Buffer Empty This bit indicates whether the receive buffer is empty. 0_B The receive buffer is not empty. 1_B The receive buffer is empty. |
| RFULL | 4 | rh | Receive Buffer Full This bit indicates whether the receive buffer is full. 0_B The receive buffer is not full. 1_B The receive buffer is full. |
| RBUS | 5 | rh | Receive Buffer Busy This bit indicates whether the receive buffer is currently updated by the FIFO handler. 0_B The receive buffer information has been completely updated. 1_B The OUTR update from the FIFO memory is ongoing. A read from OUTR will be delayed. FIFO pointers from the previous read are not yet updated. |
| SRBT | 6 | rh | Standard Receive Buffer Event Trigger This bit triggers a standard receive buffer event when set. If enabled by $RBCTR.SRBIEN$, the service request output SRx selected by $RBCTR.SRBINP$ becomes activated until the bit is cleared. 0_B A standard receive buffer event is not triggered using this bit. 1_B A standard receive buffer event is triggered using this bit. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|------|------|---|
| STBI | 8 | rwh | Standard Transmit Buffer Event This bit indicates that a standard transmit buffer event has been detected. It is cleared by writing <code>TRBSCR.CSTBI = 1</code> . If enabled by <code>TBCTR.STBIEN</code> , the service request output <code>SRx</code> selected by <code>TBCTR.STBINP</code> becomes activated if a standard transmit buffer event is detected. 0_B A standard transmit buffer event has not been detected. 1_B A standard transmit buffer event has been detected. |
| TBERI | 9 | rwh | Transmit Buffer Error Event This bit indicates that a transmit buffer error event has been detected. It is cleared by writing <code>TRBSCR.CTBERI = 1</code> . If enabled by <code>TBCTR.TBERIEN</code> , the service request output <code>SRx</code> selected by <code>TBCTR.ATBINP</code> becomes activated if a transmit buffer error event is detected. 0_B A transmit buffer error event has not been detected. 1_B A transmit buffer error event has been detected. |
| TEMPTY | 11 | rh | Transmit Buffer Empty This bit indicates whether the transmit buffer is empty. 0_B The transmit buffer is not empty. 1_B The transmit buffer is empty. |
| TFULL | 12 | rh | Transmit Buffer Full This bit indicates whether the transmit buffer is full. 0_B The transmit buffer is not full. 1_B The transmit buffer is full. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|-------------------------|------|--|
| TBUS | 13 | rh | Transmit Buffer Busy This bit indicates whether the transmit buffer is currently updated by the FIFO handler. 0_B The transmit buffer information has been completely updated. 1_B The FIFO memory update after write to INx is ongoing. A write to INx will be delayed. FIFO pointers from the previous INx write are not yet updated. |
| STBT | 14 | rh | Standard Transmit Buffer Event Trigger This bit triggers a standard transmit buffer event when set. If enabled by TBCTR.STBIEN, the service request output SRx selected by TBCTR.STBINP becomes activated until the bit is cleared. 0_B A standard transmit buffer event is not triggered using this bit. 1_B A standard transmit buffer event is triggered using this bit. |
| RBFLVL | [22:16] | rh | Receive Buffer Filling Level This bit field indicates the filling level of the receive buffer, starting with 0 for an empty buffer. |
| TBFLVL | [30:24] | rh | Transmit Buffer Filling Level This bit field indicates the filling level of the transmit buffer, starting with 0 for an empty buffer. <i>Note: The first data word written to Transmit FIFO will be loaded immediately to TBUF and removed from FIFO.</i> |
| 0 | 7, 10, 15, 23, 31 | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

The bits in register TRBSCR are used to clear the notification bits in register TRBSR or to clear the FIFO mechanism for the transmit or receive buffer. A read action always delivers 0.

Universal Serial Interface Channel (USIC)

14.11.9.5 FIFO Buffer Data Registers

The 32 independent data input locations IN00 to IN31 are addresses that can be used as data entry locations for the transmit FIFO buffer. Data written to one of these locations will be stored in the transmit buffer FIFO. Additionally, the 5-bit coding of the number [31:0] of the addressed data input location represents the transmit control information TCI.

If the FIFO is already full and new data is written to it, the write access is ignored and a transmit buffer error event is signaled.

INx (x = 00-31)

Transmit FIFO Buffer Input Location x

(180_H + x * 4)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| TDATA | [15:0] | w | Transmit Data This bit field contains the data to be transmitted (write view), read actions deliver 0. A write action to at least the low byte of TDATA triggers the data storage in the FIFO. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

The receiver FIFO buffer output register OUTR shows the oldest received data word in the FIFO buffer and contains the receiver control information RCI containing the information selected by RBCTR.RCIM. A read action from this address location delivers the received data. With a read access of at least the low byte, the data is declared to be read and the next entry becomes visible. Write accesses to OUTR are ignored.

| Field | Bits | Type | Description |
|-------|---------|------|---|
| DSR | [15:0] | rh | Received Data This bit field monitors the content of the oldest data word in the receive FIFO. Reading at least the low byte releases the buffer entry currently shown in DSR. |
| RCI | [20:16] | rh | Receiver Control Information This bit field monitors the receiver control information associated to DSR. The bit structure of RCI depends on bit field RBCTR.RCIM. |
| 0 | [31:21] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

If a debugger should be used to monitor the received data in the FIFO buffer, the FIFO mechanism must not be activated in order to guaranty data consistency. Therefore, a second address set is available, named OUTDR (D like debugger), having the same bit fields like the original buffer output register OUTR, but without the FIFO mechanism. A debugger can read here (in order to monitor the receive data flow) without the risk of data corruption. Write accesses to OUTDR are ignored.

OUTDR

Receiver Buffer Output Register L for Debugger

(120_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| DSR | [15:0] | rh | Data from Shift Register Same as OUTR.DSR, but without releasing the buffer after a read action. |
| RCI | [20:16] | rh | Receive Control Information from Shift Register Same as OUTR.RCI. |
| 0 | [31:21] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)
14.11.9.6 FIFO Buffer Pointer Registers

The pointers for FIFO handling of the transmit and receive FIFO buffers are located in register TRBPTR. The pointers are automatically handled by the FIFO buffer mechanism and do not need to be modified by software. As a consequence, these registers can only be read by software (e.g. for verification purposes), whereas write accesses are ignored.

TRBPTR
Transmit/Receive Buffer Pointer Register
(110_H)
Reset Value: 0000 0000_H

Universal Serial Interface Channel (USIC)

14.12 Interconnects

The XMC1100 device contains one USIC module (USIC0) with 2 communication channels.

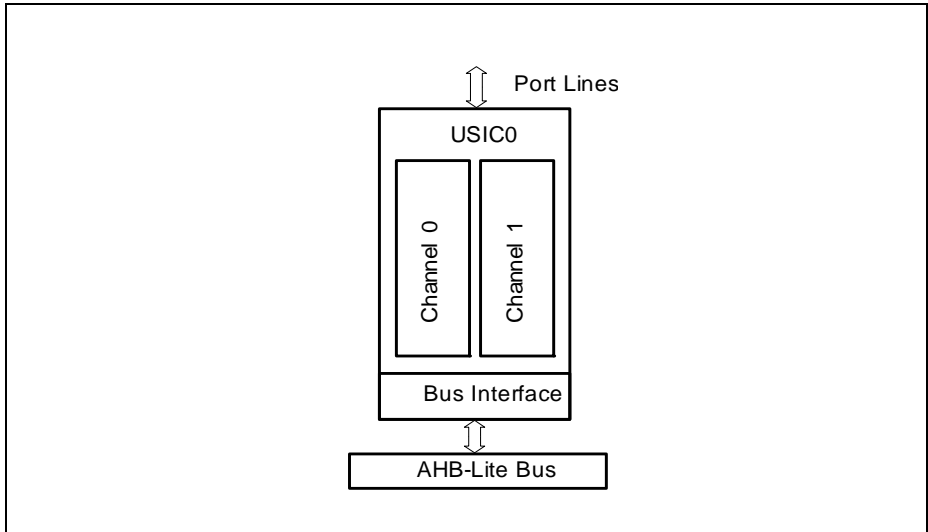

Figure 14-66 USIC Module Structure in XMC1100

Figure 14-67 shows the I/O lines of one USIC channel. The tables in this section define the pin assignments and internal connections of the USIC channels I/O lines in the XMC1100 device. Naming convention: USICx_CHy refers to USIC module x channel y. The meaning of these pins with respect to each protocol is described in the protocols' respective chapters and summarized in [Table 14-2](#) and [Table 14-3](#).

Universal Serial Interface Channel (USIC)

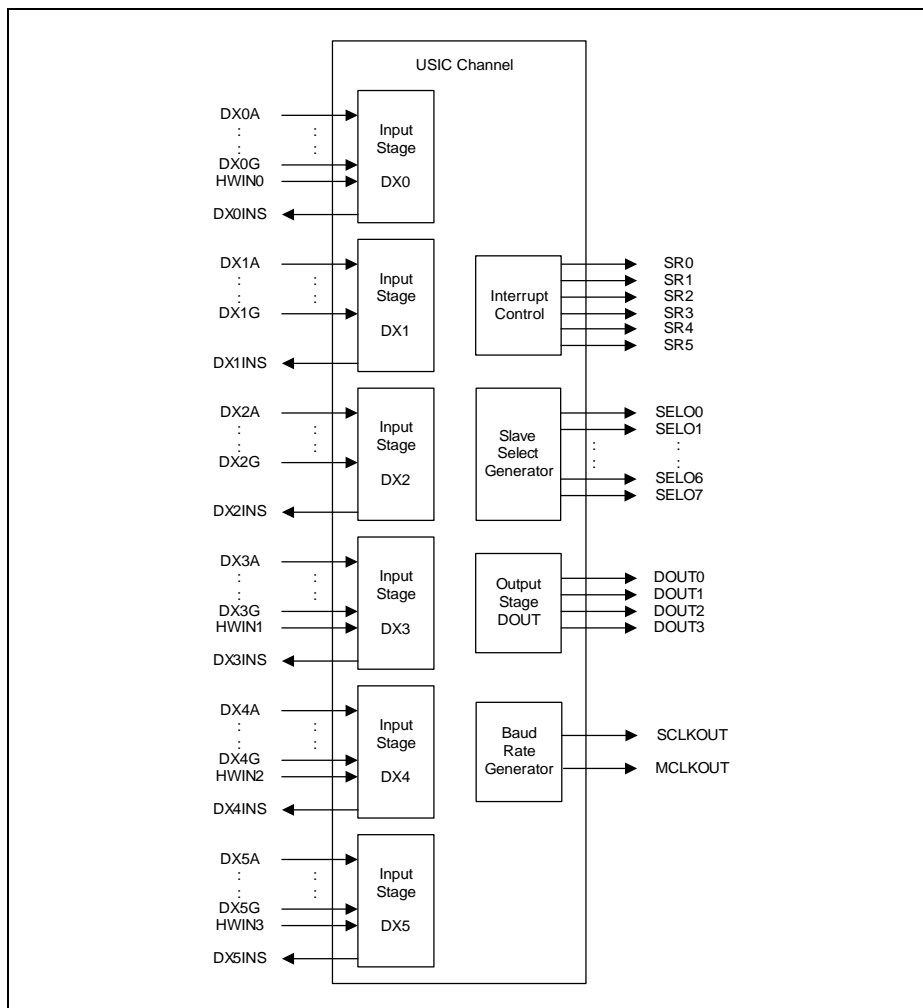

Figure 14-67 USIC Channel I/O Lines

The service request outputs SR[5:0] of one USIC channel is combined with those of the other channel with the module. Therefore, only 6 service request outputs are available per module.

14.12.1 USIC Module 0 Interconnects

The interconnects of USIC module 0 is grouped into the following categories:

Universal Serial Interface Channel (USIC)

- **USIC Module 0 Channel 0 Interconnects** (Table 14-23)
- **USIC Module 0 Channel 1 Interconnects** (Table 14-24)
- **USIC Module 0 Module Interconnects** (Table 14-25)

15 Analog-to-Digital Converter (VADC)

The analog-to-digital converter (ADC) in XMC1100 series provides a subset of functions compared to the feature-rich VADC (versatile analog-to-digital converter) which is implemented in XMC1200 and XMC1300 series.

The XMC1100 provides a series of analog input channels combined into two groups. The ADC is based on a high-speed 12-Bit converter clocked at 32 MHz using the successive approximation register (SAR) principle to convert analog input values (voltages) to discrete digital values. Each analog input channel can be configured to be amplified by an adjustable gain factor. Conversion mode and sampling time can be configured for each group in order to meet the requirements of the application.

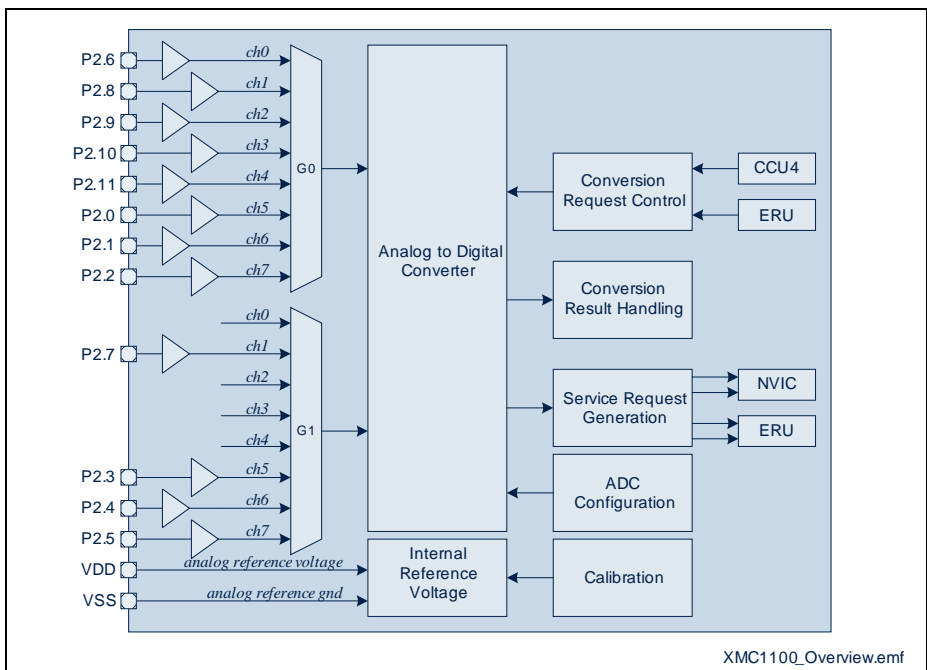

Figure 15-1 Block Diagram

The reference voltage of the ADC is internally generated and can be automatically calibrated to the supply voltage of the device. If required, additional calibration steps can be automatically performed after each conversion.

The ADC offers two first-order sigma-delta loops which can be assigned to any of the input channels ([Section 15.1.3](#)). They hold the quantization error of the previous conversion in order to automatically consider this tiny amount of charge in the next

Analog-to-Digital Converter (VADC)

conversion. This will increase the Effective Number Of Bits (ENOB) while implementing oversampling algorithms.

The Conversion Request Control Unit ([Section 15.2](#)) controls the sampling and conversion of the analog input signal. Conversions of single channels as well as a scan of selected channels can be configured. The start of the conversion sequence is either a software command or a hardware trigger from an interconnected peripheral or a signal at a port pin.

The conversion result is provided in a result register with a wait-for-read option. The wait-for-read mode avoids data loss due to premature result overwrite, by blocking a conversion until the previous result has been read. Automatic accumulation of consecutive measurements can be performed by the data reduction filter which is described in [Section 15.4.4](#).

Flexible service request generation is based on selectable events which can be routed to two interrupts.

- **Source events** indicate the completion of a conversion sequence in the corresponding request source. This event can be used to trigger the setup of a new sequence.
- **Result events** indicate the availability of new result data in the corresponding result register. If data reduction mode is active, events are generated only after a complete accumulation sequence.

Each event can be assigned to one of four service request nodes. This allows grouping the requests according to the requirements of the application.

15.1 Analog Module Activation and Control

The analog converter of the ADC is the functional block that generates the digital result values from the selected input voltage. It draws a permanent current during its operation and can be deactivated between conversions to reduce the consumed overall energy.

Note: After reset, the analog converters are off. They must be enabled before triggering any action involving the converter.

15.1.1 Analog Converter Control

Bit ANOFF in register **SHS0_SHSCFG** forces the analog part into power-down mode, without changing the configuration of the associated groups. While ANOFF = 0, the analog part is enabled.

Wakeup Time from Analog Powerdown

When the converter is activated (ANOFF = 0), it needs a certain wakeup time to settle before a conversion can be properly executed. This wakeup time can be established by waiting the required period before starting a conversion.

15.1.2 Calibration

Calibration compensates deviations caused by process, temperature, and voltage variations. This ensures accurate results throughout the operation time.

Several different calibration cycles are executed for offset and gain calibration. These calibration cycles are executed alternating after a conversion.

An initial startup calibration is required once after a reset. First, the converter must be enabled (ANOFF = 0_B), then the startup calibration can be initiated by setting bit SUCAL in register **GLOBCFG** or in register **SHS0_CALCTR**. Conversions may be started after the initial calibration sequence. This is indicated by parameter **SHS0_SHSCFG.STATE** which can be polled by software.

The start-up calibration phase takes 1920 cycles ($1920 \times 31.25 \text{ ns} = 60 \mu\text{s}$).

After that, calibration cycles will compensate the effects of drifting parameters. The calibration cycles can be executed before or after (user configuration) a conversion sequence or can be disabled.

A calibration timer automatically triggers calibration cycles during idle phases of the ADC. This ensures the specified performance even after an idle phase.

Note: The ADC error depends on the temperature. Therefore, the calibration must be repeated periodically.

Maximum Calibration Interval

While no conversions are requested, the stepper remains in its idle state. In order not to lose accuracy, a counter counts the time since the last executed calibration. This timer is loaded after each calibration with the start value from bitfield CALCTR.CALMAX and counts $128 \times (\text{CALMAX} + 1)$ clocks. If it expires it generates a calibration request which starts the stepper to execute a calibration cycle.

15.1.3 Sigma-Delta-Loop Function

Each standard analog-to-digital conversion incurs a quantization error due to the limited number of steps i.e. discrete result values. By activating the sigma-delta-loop function this residual quantization error can be forwarded to the next conversion. The residual charge is stored and added to the next sampled charge. Averaging successive conversion results (with the loop enabled) can, therefore, reduce the quantization error.

Note: The data accumulation function (see [Section 15.4.4](#)) supports this averaging.

The loop control bitfields are available in pairs in register [SHS0_LOOP](#).

15.2 Conversion Request Generation

The conversion request unit of a group autonomously handles the generation of conversion requests.

- **Software triggers**
directly activate the request source and requests a conversion.
- **External triggers**
an external signal can act as conversion trigger request. As a result it synchronizes the request source activation with external events, such as a trigger pulse from a timer generating a PWM signal, or from a port pin.
- **External gating**
an external signal can block a conversion request.

Application software selects the trigger type and source (**BRSCtrl**), the gating mechanism (**BRSMR**) and the channel(s) to be converted (**BRSELx (x = 0 - 1)**). The request source can also be activated directly by software (**BRSMR.LDEV = 1**) without requiring an external trigger. The conversion request is then forwarded to the converter to start the sampling and conversion of the requested channel. **Figure 15-2** gives an overview to the conversion request source.

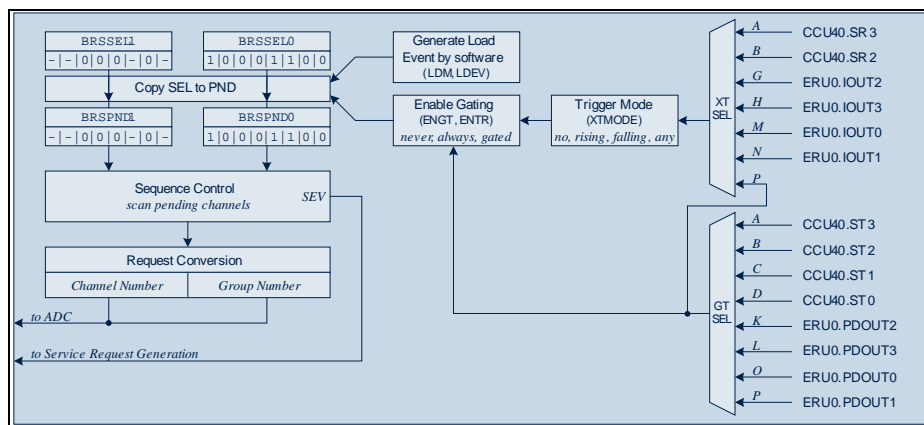

Figure 15-2 Conversion Request Source

The request source can operate in single-shot (scan mode) or in continuous mode (autoscan mode):

- **In single-shot mode,**
the programmed conversion (sequence) is requested once after being triggered. A subsequent conversion (sequence) must be triggered again.
- **In continuous mode,**
the programmed conversion (sequence) is automatically requested repeatedly after being triggered once.

Analog-to-Digital Converter (VADC)

External triggers are generated from one of 15 selectable trigger inputs (REQTRx[P:A]) and from one of 16 selectable gating inputs (REQGTx[P:A]). The available trigger signals for the XMC1100 are listed in [Section 15.7.3](#).

15.2.1 Channel Scan Request Source Handling

Each analog input channel can be included in or excluded from the scan sequence by setting or clearing the corresponding channel select bit in register **BRSELx (x = 0 - 1)**. The programmed register value remains unchanged by an ongoing scan sequence. The scan sequence starts with the highest enabled channel number and continues towards lower channel numbers.

Upon a load event which is triggered by hardware signals or software, the request pattern is transferred to the pending bits in register **BRSPNDx (x = 0 - 1)**. The pending conversion requests indicate which input channels are to be converted in an ongoing scan sequence. Each conversion start that was triggered by the scan request source, automatically clears the corresponding pending bit. If the last conversion triggered by the scan source is finished and all pending bits are cleared, the current scan sequence is considered finished and a request source event (REV) is generated.

The trigger and gating unit generates load events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Load events start a scan sequence and can be generated either via software or via the selected hardware triggers. The request source event can also generate an automatic load event, so the programmed sequence is automatically repeated.

Scan Source Operation

Configure the scan request source by executing the following actions:

- Select the input channels for the sequence by programming **BRSELx (x = 0 - 1)**
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper signal transitions by programming **BRCTRL**. Enable the trigger and select the gating mode by programming **BRSMR**.¹⁾
- Define the load event operation (handling of pending bits, autoscan mode) by programming **BRSMR**.

A load event with bit LDM = 0 copies the content of **BRSELx (x = 0 - 1)** to **BRSPNDx (x = 0 - 1)** (overwrite mode). This starts a new scan sequence and aborts any pending conversions from a previous scan sequence.

A load event with bit LDM = 1 OR-combines the content of **BRSELx (x = 0 - 1)** to

1) If PDOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid unexpected signal transitions.

Analog-to-Digital Converter (VADC)

BRSPNDx (x = 0 - 1) (combine mode). This starts a scan sequence that includes pending conversions from a previous scan sequence.

Start a channel scan sequence by generating a load event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- or: Generate a software load event by setting LDEV = 1 (**BRSMR**)
- or: Generate a load event by writing the scan pattern directly to the pending bits in **BRSPNDx (x = 0 - 1)**. The pattern is copied to **BRSELx (x = 0 - 1)** and a load event is generated automatically.

In this case, a scan sequence can be defined and started with a single data write action (provided that the pattern fits into one register).

Note: If autoscan is enabled, a load event is generated automatically each time a request source event occurs when the scan sequence has finished. This permanently repeats the defined scan sequence (autoscan).

Stop or abort an ongoing scan sequence by executing one of the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the conversion pending bits, but only prevents issuing conversion requests to the ADC.
- Disable the channel scan source by clearing bitfield ENGT = 00_B. Clear the pending request bits by setting bit CLRPND = 1 (**BRSMR**).

Scan Request Source Events and Interrupt Service Requests

A request source event of a scan source occurs when the last conversion of a scan sequence is finished (all pending bits = 0). A request source event interrupt can be generated based on a request source event. If a request source event is detected, it sets the corresponding indication flag in register **GLOBEFLAG**. This flag can also be set by writing 1 to the corresponding bit position, whereas writing 0 has no effect.

The service request output SRx that is selected by the request source event interrupt node pointer bitfields in register **GLOBEVNP** becomes activated each time the related request source event is detected (and enabled by ENSI) or the related bit position in register **GLOBEFLAG** is written with 1 (this write action simulates a request source event).

The indication flags can be cleared by SW by writing 1 to the corresponding bit position in register **GLOBEFLAG**.¹⁾

1) Please refer to “**Service Request Generation**” on Page 15-14.

15.3 Analog Input Channel Configuration

The analog input channels are assigned to one of two groups. For each group a number of parameters can be configured in register **GLOBICLASSy (y = 0 - 1)** that control the conversion of the channels.

15.3.1 Conversion Modes

A conversion can be executed in several ways. The conversion mode is selected according to the requested resolution of the digital result and according to the acceptable conversion time (**Section 15.3.2**).

Use bitfield CMS in register **GLOBICLASSy (y = 0 - 1)** to select a mode.

Standard Conversions

A standard conversion returns a result value with a predefined resolution. 8-bit, 10-bit, and 12-bit resolution can be selected.

These result values can be accumulated.

Fast Compare Mode

In Fast Compare Mode, the selected input voltage is directly compared with a digital value that is stored in the result register. This compare operation returns a binary result indicating the compared input voltage is above or below the given reference value. This result is generated quickly and thus supports monitoring of boundary values.

Fast Compare Mode uses a 10-bit compare value stored left-aligned at bit position 11.

15.3.2 Conversion Timing

The total time required for a conversion comprises the time from the start of the sample phase¹⁾ until the availability of the result.

The timing basis are the module clock f_{ADC} (derived from MCLK) and the converter clock f_{SH} (typically 32 MHz).

The sample rate at which consecutive conversions are triggered also depends on several configurable factors:

- The conversion time, according to the selected conversion mode.
- The frequency of external trigger signals, if enabled.

The sample time can be adjusted according to the application requirements. Use bitfield STC in register **GLOBICLASSy (y = 0 - 1)** to adjust the sample time.

The conversion time is the sum of sample time and conversion time. It can be computed with the following formula:

$$t_{CN} = (2 + STC) \times 2 \times t_{ADC} + 4 \times t_{SH} + (N + 8) \times t_{SH} + 5 \times t_{ADC}$$

A conversion round comprises a conversion and a calibration step. Calibration steps are executed after each conversion (up to $12 \times t_{SH}$)²⁾, so the maximum complete conversion round will take:

$$t_{CR} = (2 + STC) \times 2 \times t_{ADC} + 4 \times t_{SH} + (N + 8) \times t_{SH} + 5 \times t_{ADC} + 12 \times t_{SH}$$
²⁾

Timing Examples

System assumptions:

$$f_{ADC} = f_{SH} = 32 \text{ MHz i.e. } t_{ADC} = t_{SH} = 31.25 \text{ ns}$$

According to the given formula the following minimum conversion times can be achieved:

12-bit conversion:

$$t_{CN12C} = 2 \times 2 \times t_{ADC} + 4 \times t_{SH} + (12 + 8) \times t_{SH} + 5 \times t_{ADC} = 33 \times 31.25 \text{ ns} = 1\,032 \text{ ns}$$

10-bit conversion:

$$t_{CN10C} = 2 \times 2 \times t_{ADC} + 4 \times t_{SH} + (10 + 8) \times t_{SH} + 5 \times t_{ADC} = 31 \times 31.25 \text{ ns} = 969 \text{ ns}$$

The maximum time for an isolated conversion will take up to:

$$t_{C1} = 1\,032 \text{ ns} + 12 \times 31.25 \text{ ns} = 1\,407 \text{ ns (12-bit conversion)}$$
³⁾

1) The time from the trigger event that requests the corresponding conversion until the start of the sample phase depends on propagation delays of the selected trigger signal.

2) Offset and gain calibration steps are executed alternating, where gain calibration takes more time than offset calibration (9 cycles).

3) 12 calibration clock cycles are the maximum resulting from a gain calibration step.

15.4 Conversion Result Handling

The A/D converters can preprocess the conversion result data to a certain extent before storing them for retrieval by the CPU. This supports the subsequent handling of result data by the application software.

Conversion result handling comprises the following functions:

- **Storage of Conversion Results** and **Data Alignment**
- **Wait-for-Read Mode** to avoid loss of data
- **Result Event Generation**
- **Data Modification**

15.4.1 Storage of Conversion Results

The conversion result values are stored in the result register (**GLOBRES**).

The result register has an individual data valid flag (VF) associated with it. This flag indicates when “new” valid data has been stored in the result register and can be read out.

For standard conversions, result values are available in bitfield RESULT. Conversions in Fast Compare Mode use bitfield RESULT for the reference value, so the result of the operation is stored in bit FCR.

The result register can be read via two different views. These views use different addresses but access the same register data:

- When the result register is read via the **application view (GLOBRES)**, the corresponding valid flag is automatically cleared when the result is read. This provides an easy handshake between result generation and retrieval. This also supports wait-for-read mode.
- When the result register is read via the **debug view (GLOBRESD)**, the corresponding valid flag remains unchanged when the result is read. This supports debugging by delivering the result value without disturbing the handshake with the application.

15.4.1.1 Data Alignment

The position of a conversion result value within the selected result register depends on two configurations:

- The selected result width (12/10/8 bits, see [Section 15.3.1](#))
- The selected data accumulation mode (data reduction, see [Section 15.4.4](#))

These options provide the conversion results in a way that minimizes data handling for the application software.

| Bit in Result Register | | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|------------------------|---------------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Standard Conversion | 12-Bit | 0 | 0 | 0 | 0 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | 10-Bit | 0 | 0 | 0 | 0 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 |
| | 8-Bit | 0 | 0 | 0 | 0 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 | 0 | 0 |
| | 10-Bit fast compare | 0 | 0 | 0 | 0 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 |
| Accumulated Conversion | 12-Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | 10-Bit | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 |
| | 8-Bit | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 | 0 | 0 |

Figure 15-3 Result Register Data Alignment

Bitfield RESULT of register **GLOBRES** must be written by SW with the wanted reference comparison value for Fast Compare Mode. In this mode, bits 11-2 are evaluated, the other bits are ignored.

15.4.2 Wait-for-Read Mode

The wait-for-read mode (**GLOBRCR.WFR** = 1) prevents data loss due to overwriting the result register with a new conversion result before the CPU has read the previous data. Since the results come from different input channels, an overwrite may destroy the result from the previous conversion.

Wait-for-read mode automatically suspends the start of a conversion until the current result has been read. As a result, a conversion or a conversion sequence can be requested by a hardware or software trigger, while each conversion is only started after the result of the previous one has been read. This automatically aligns the conversion sequence with the CPU capability to read the formerly converted result (latency).

15.4.3 Result Event Generation

A result event can be generated when a new value is stored in the result register. Result events can be restricted due to data accumulation and can be generated only if the accumulation is complete.

Result events can also be suppressed completely.

15.4.4 Data Modification

The data resulting from conversions can be automatically modified before being used by an application.

The data reduction mode can be used as a digital filter for anti-aliasing or decimation purposes. It accumulates a maximum of 4 conversion values to generate a final result.

The result register can be configured for data reduction, controlled by bitfield **GLOBRCCR.DRCTR**.

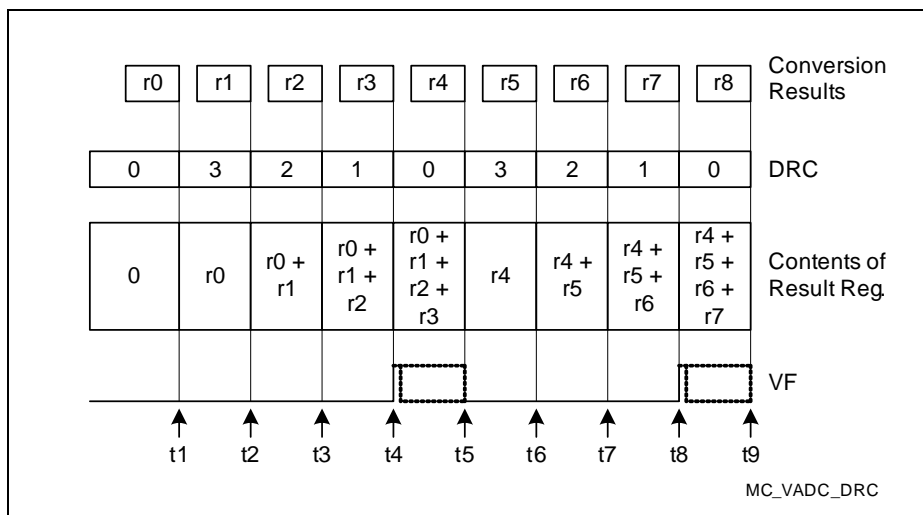

Figure 15-4 Standard Data Reduction Filter

This example shows a data reduction sequence of 4 accumulated conversion results. Eight conversion results (r0 ... r7) are accumulated and produce 2 final results.

When a conversion is complete, data is stored in the result register with data reduction mode enabled, and the data handling is controlled by the data reduction counter DRC:

- If DRC = 0 (t1, t5, t9 in the example), the conversion result is stored to the result register. DRC is loaded with the contents of bitfield DRCTR (i.e. the accumulation begins).

Analog-to-Digital Converter (VADC)

- If $DRC > 0$ (t2, t3, t4 and t6, t7, t8 in the example), the conversion result is added to the value in the result register.
DRC is decremented by 1.
- If DRC becomes 0, either decremented from 1 (t4 and t8 in the example) or loaded from DRCTR, the valid bit for the respective result register is set and a result register event occurs.
The final result must be read before the next data reduction sequence starts (before t5 or t9 in the example). This automatically clears the valid flag.

Note: The data reduction filter may be used with a single channel only unless averaging of several channels is intended.

15.5 Service Request Generation

Each A/D Converter group can activate up to 4 shared service request output signals. 2 shared request signals can issue an interrupt, see [Table 15-5 “Digital Connections in the XMC1100” on Page 15-42](#).

Several events can be assigned to each service request output. Service requests can be generated by three types of events:

- **Request source events (SEV):** indicate that the request source completed the requested conversion sequence and the application software can initiate further actions. The event is generated when the complete defined set of channels (pending bits) has been converted.
- **Result events (REV):** indicate a new valid result in the result register. Usually, this triggers a read action by the CPU. Optionally, result events can be generated only at a reduced rate if data reduction is active.

Each ADC event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures that the ADC event can generate a service request without the need to clear the indication flag.

Event flag registers indicate all types of events that occur during the ADC's operation. Software can set/clear each flag by writing a 1 to the respective position in register **GLOBEFLAG** to trigger/clear an event. If enabled, service requests are generated for each occurrence of an event, even if the associated flag remains set.

Node Pointer Registers

Requests from each event source can be directed to a set of service request nodes via associated node pointers. Requests from several sources can be directed to the same node; in this case, they are ORed to the service request output signal.

Analog-to-Digital Converter (VADC)

15.6 Registers

The register map of the ADC is built from two blocks, the VADC0 and the SHS0. The corresponding registers, therefore, have an individual offset assigned (see [Table 15-2](#)). The exact register location is obtained by adding the respective register offset to the base address (see [Table 15-1](#)) of the corresponding block.

Table 15-1 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| VADC0 | 4803 0000 _H | 4803 03FF _H | |
| SHS0 | 4803 4000 _H | 4803 41FF _H | |

| Field | Bits | Type | Description |
|------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Indicates the revision number of the implementation. This information depends on the design step. |
| MOD_TYPE | [15:8] | r | Module Type This internal marker is fixed to C0 _H . |
| MOD_NUMBER | [31:16] | r | Module Number Indicates the module identification number (00C5 _H = SARADC, 0099 _H = SHS). |

15.6.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. Register **CLC** controls the module clock signal and the reactivity to the sleep mode signal.

CLC

Clock Control Register

| 0 | [31:4] | r | Reserved, write 0, read as 0 |

Analog-to-Digital Converter (VADC)

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging).

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.

When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

| rw | rw | | | | rw | | | r | r | r | r | r | r | rw | rw |

| Field | Bits | Type | Description |
|---------------|------|------|--|
| CALORD | 0 | rw | Calibration Order 0 _B Do conversions then calibration 1 _B Do calibration then conversions |
| RANCAL | 1 | rw | Random Calibration 0 _B Calibrate after each conversion round 1 _B Randomly shift calibration after a conversion round <i>Note: Random calibration is only supported for postcalibration, i.e. CALORD = 0.</i> |

Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| 0 | [7:2] | r | Reserved, write 0, read as 0 |
| CALGNSTC | [13:8] | rw | Gain Calibration Sample Time Control Defines the duration of the sample phase for gain calibration cycles. 00 _H Reserved Others: $t_{SGN} = \text{CALGNSTC} / f_{SH}$ ¹⁾ |
| OCDIS | 14 | rw | Offset Calibration Disable 0 _B Standard calibration 1 _B Exclude offset calibration steps from the sequence |
| GCDIS | 15 | rw | Gain Calibration Disable 0 _B Standard calibration 1 _B Exclude gain calibration steps from the sequence |
| SUCALVAL | [22:16] | rw | Startup Calibration Cycles Defines the number of calibration sequences for the startup calibration. <i>Note: No user control required.</i> |
| CALMAX | [29:24] | rw | Calibration Maximum Timing Defines the maximum time until the next calibration: $t_{MAX} = 128 / f_{SH} \times (\text{CALMAX} + 1)$ |
| 0 | 30 | r | Reserved, write 0, read as 0 |
| SUCAL | 31 | w | Start-Up Calibration The 0-1 transition of bit SUCAL triggers the start-up calibration phase of the converter. ²⁾ SUCAL is cleared automatically when the calibration phase begins. 0 _B No action 1 _B Initiate the start-up calibration phase (indication in bitfield SHSCFG.STATE) |

1) If the internal reference is used in the lower voltage range, also the sample time for gain calibration must be enlarged. In this case, set CALCTR.CALGNSTC to 12_D.

2) Startup calibration can also be triggered by the known bit SUCAL in register GLOB_CFG in module VADC_DIG.

Analog-to-Digital Converter (VADC)

The gain control registers GNCTR_{x0} select the gain level for each input.

SHS0_GNCTR00

Gain Control Register 00

(4803 4180_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------|---------|------|---|
| SEVGLB | 0 | rwh | Source Event 0 _B No source event 1 _B A source event has occurred |
| 0 | [7:1] | r | Reserved, write 0, read as 0 |
| REVGLB | 8 | rwh | Result Event 0 _B No result event 1 _B New result was stored in register GLOBRES |
| 0 | [15:9] | r | Reserved, write 0, read as 0 |
| SEVGLBCLR | 16 | w | Clear Source Event 0 _B No action 1 _B Clear the source event flag SEVGLB |
| 0 | [23:17] | r | Reserved, write 0, read as 0 |
| REVGLBCLR | 24 | w | Clear Result Event 0 _B No action 1 _B Clear the result event flag REVGLB |
| 0 | [31:25] | r | Reserved, write 0, read as 0 |

Note: Software can set flags REVGLB and SEVGLB and trigger the corresponding event by writing 1 to the respective bit. Writing 0 has no effect.

Software can clear these flags by writing 1 to bit REVGLBCLR and SEVGLBCLR, respectively.

Analog-to-Digital Converter (VADC)

Setting both bits (e.g. SEVGLB and SEVGLBCLR) simultaneously clears the corresponding flag (e.g. SEVGLB).

15.7 Interconnects

This section describes the actual implementation of the VADC module into the XMC1100, i.e. the incorporation into the microcontroller system.

15.7.1 Product-Specific Configuration

The functional description describes the features and operating modes of the A/D Converters in a general way. This section summarizes the configuration that is available in this product (XMC1100).

15.7.2 Analog Module Connections in the XMC1100

The VADC module accepts a number of analog input signals. The analog input multiplexers select the input channels from the signals available in this product.

The exact number of analog input channels and the available connection to port pins depend on the employed product type. A summary of channels enclosing all versions of the XMC1100 can be found in [Table 15-4](#).

Table 15-4 Analog Connections in the XMC1100

| Signal | Dir. | Source/Destin. | Description |
|---|------|----------------|-----------------------------------|
| Reference Voltage Pins | | | |
| V_{AREF} | I | VDD | positive analog reference |
| V_{AGND} | I | VSS | negative analog reference |

15.7.3 Digital Module Connections in the XMC1100

The VADC module accepts a number of digital input signals and generates a number of output signals. This section summarizes the connection of these signals to other on-chip modules or to external resources via port pins.

Note: The control bitfields for triggers and gates select the corresponding multiplexer input. Values 0000_B ... 1111_B select inputs with suffix -A ... -P.

16 Temperature Sensor (TSE)

This chapter describes the controls for Temperature Sensor (TSE).

16.1 General Description

The Temperature Sensor (TSE) generates a measurement result that indicates directly the current temperature. The result of the measurement is displayed via bit field ANATSEMON.TSE_MON. The user routines (_CalcTemperature) inside ROM takes this value and calculate the actual silicon temperature. This routine can be called by the application software and more details are described in Chapter “Bootstrap Loaders and User Routines”. Library functions are also available and described in the Temperature Sensor device guide. The TSE has to be enabled before it can be used via bit ANATSECTRL.TSE_EN.

The measurement result is ready when the SRRAW.TSE_DONE flag is set. An interrupt can be triggered when it is enabled via SRMSK.TSE_DONE bit. After the measurement is completed and result is stored in TSE_MON, TSE continue with next measurement. Measurement are disabled when TSE_EN is cleared to 0. Hence, reading the TSE_MON value will provide you the latest temperature.

The TSE is capable of generating interrupt requests when TSE temperature measurement in result crosses upper and/or lower threshold value configured in bit ANATSEIH.TSE_IH and ANATSEIL.TSE_IL respectively. Digital comparators are implemented to compare the actual measurement result against configured limits and triggers interrupt if the value fall outside of valid range. Result of comparison is shown as the SRRAW.TSE_HIGH and TSE_LOW flag. The user routines (_CalcTSEVAR) can be used to obtain the upper and lower temperature limits needed to program the bit TSE_IH and TSE_IL and more details are described in Chapter “Bootstrap Loaders and User Routines”. Library functions are also available and described in the Temperature Sensor device guide.

16.2 Service Request Generation

The TSE has a service request output for TSE Done, TSE HIGH and TSE Low event. They are combined with events from other modules into a single output and connected to one of the interrupt node in the Nested Vectored Interrupt Controller (NVIC) via SCU.SR1.

The service request handling is part of the GCU block in SCU module. Refer to the “Service Request” description in the GCU section which is part of the SCU chapter for more details.

16.3 Registers

TSE registers are accessible via the APB bus. The absolute register address is calculated by adding:

Module Base Address + Offset Address

Following access to TSE SFRs result in an AHB/APB error response:

- Read or write access to undefined address
- Write access to read-only registers

Table 16-1 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|-------------------------------|
| TSE | 4001 0000 _H | 4001 FFFF _H | System Control Unit Registers |

Table 16-2 Registers Overview

| Short Name | Description | Offset Addr. ¹⁾ | Access Mode | | Description See |
|------------|--|----------------------------|-------------|-------|---------------------------|
| | | | Read | Write | |
| ANATSECTRL | Temperature Sensor Control Register | 0024 _H | U, PV | U, PV | Page 16-3 |

|---------|------|------|---|
| TSE_MON | 15:0 | rh | Monitor Counter2 value; loaded by TSE_DONE After each measurement done event (indicated by a set in SCU_SRRAW.TSE_DONE bit), the result is stored in this register. |

17 Capture/Compare Unit 4 (CCU4)

The CCU4 peripheral is a major component for systems that need general purpose timers for signal monitoring/conditioning and Pulse Width Modulation (PWM) signal generation. Power electronic control systems like switched mode power supplies or uninterruptible power supplies, can easily be implemented with the functions inside the CCU4 peripheral.

The internal modularity of CCU4, translates into a software friendly system for fast code development and portability between applications.

Table 17-1 Abbreviations table

| | |
|------------|---|
| PWM | Pulse Width Modulation |
| CCU4x | Capture/Compare Unit 4 module instance x |
| CC4y | Capture/Compare Unit 4 Timer Slice instance y |
| ADC | Analog to Digital Converter |
| POSIF | Position Interface peripheral |
| SCU | System Control Unit |
| f_{ccu4} | CCU4 module clock frequency |
| f_{tclk} | CC4y timer clock frequency |

Note: A small “y” or “x” letter in a register indicates an index

17.1 Overview

Each CCU4 module is comprised of four identical 16 bit Capture/Compare Timer slices, CC4y. Each timer slice can work in compare mode or in capture mode. In compare mode one compare channel is available while in capture mode, up to four capture registers can be used in parallel.

Each CCU4 module has four service request lines and each timer slice contains a dedicated output signal, enabling the generation of up to four independent PWM signals. Straightforward timer slice concatenation is also possible, enabling up to 64 bit timing operations. This offers a flexible frequency measurement, frequency multiplication and pulse width modulation scheme.

A programmable function input selector for each timer slice, that offers up to nine functions, discards the need of complete resource mapping due to input ports availability.

A built-in link between the CCU4 and several other modules enable flexible digital motor control loops implementation, e.g. with Hall Sensor monitoring or direct coupling with Encoders.

17.1.1 Features

CCU4 module features

Each CCU4 represents a combination of four timer slices, that can work independently in compare or capture mode. Each timer slice has a dedicated output for PWM signal generation.

All four CCU4 timer slices, CC4y, are identical in terms of available functions and operating modes. Avoiding this way the need of implementing different software routines, depending on which resource of CCU4 is used.

A built-in link between the four timer slices is also available, enabling this way a simplified timer concatenation and sequential operations.

General Features

- 16 bit timer cells
- capture and compare mode for each timer slice
 - four capture registers in capture mode
 - one compare channel in compare mode
- programmable low pass filter for the inputs
- built-in timer concatenation
 - 32, 48 or 64 bit width
- shadow transfer for the period and compare values
- programmable clock prescaler
- normal timer mode
- gated timer mode
- three counting schemes
 - center aligned
 - edge aligned
 - single shot
- PWM generation
- TRAP function
- start/stop can be controlled by external events
- counting external events
- four dedicated service request lines per CCU4

Additional features

- external modulation function
- load controlled by external events
- dithering PWM
- floating point pre scaler
- output state override by an external event
- suitable and flexible connectivity to several modules:
 - motor and power conversion applications
 - high number of signal conditioning possibilities

CCU4 features vs. applications

On [Table 17-2](#) a summary of the major features of the CCU4 unit mapped with the most common applications.

Table 17-2 Applications summary

| Feature | Applications |
|---|---|
| Four independent timer cells | Independent PWM generation: <ul style="list-style-type: none"> • Multiple buck/boost converter control (with independent frequencies) • Different modes of operation for each timer, increasing the resource optimization • Up to 2 Half-Bridges control • multiple Zero Voltage Switch (ZVS) converter control with easy link to the ADC channels. |
| Concatenated timer cells | Easy to configure timer extension up to 64 bit: <ul style="list-style-type: none"> • High dynamic trigger capturing • High dynamic signal measurement |
| Dithering PWM | Generating a fractional PWM frequency or duty cycle: <ul style="list-style-type: none"> • To avoid big steps on frequency or duty cycle adjustment in slow control loop applications • Increase the PWM signal resolution over time |
| Floating prescaler | Automated control signal measurement: <ul style="list-style-type: none"> • decrease SW activity for monitoring signals with high or unknown dynamics • emulating more than a 16 bit timer for system control |
| Up to 9 functions via external signals for each timer | Flexible resource optimization: <ul style="list-style-type: none"> • The complete set of external functions is always available • Several arrangements can be done inside a CCU4, e.g., one timer working in capture mode and one working in compare |

Table 17-2 Applications summary (cont'd)

| Feature | Applications |
|-----------------------------------|---|
| 4 dedicated service request lines | Specially developed for: <ul style="list-style-type: none"> generating interrupts for the microprocessor flexible connectivity between peripherals, e.g. ADC triggering. |
| Linking with other modules | Flexible profiles for: <ul style="list-style-type: none"> Hall Sensor feedback/monitoring Motor Encoders feedback/monitoring PWM parallel modulation Flexible signal conditioning |

17.1.2 Block Diagram

Each CCU4 timer slice can operate independently from the other slices for all the available modes. Each timer slice contains a dedicated input selector for functions linked with external events and has a dedicated compare output signal, for PWM signal generation.

The built-in timer concatenation is only possible with adjacent slices, e.g. CC40/CC41. Combinations for slice concatenations like, CC40/CC42 or CC40/CC43 are not possible.

The individual service requests for each timer slice (four per slice) are multiplexed into four module service requests lines, [Figure 17-1](#).

Capture/Compare Unit 4 (CCU4)

Figure 17-1 CCU4 block diagram

17.2 Functional Description

17.2.1 CC4y Overview

The input path of a CCU4 slice is comprised of a selector ([Section 17.2.2](#)) and a connection matrix unit ([Section 17.2.3](#)). The output path contains a service request control unit, a timer concatenation unit and two units that control directly the state of the output signal for each specific slice (for TRAP and modulation handling), see [Figure 17-2](#).

The timer core is built of a 16 bit counter one period and one compare register in capture mode, or up to four capture registers in capture mode.

In compare mode the period register sets the maximum counting value while the compare channel is controlling the ACTIVE/PASSIVE state of the dedicated comparison slice output.

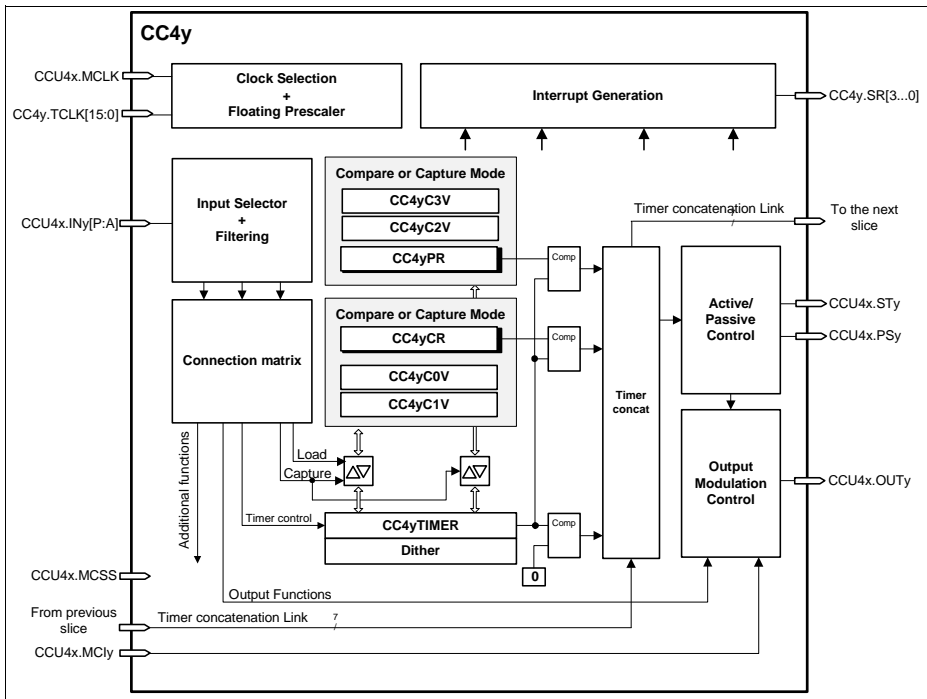

Figure 17-2 CCU4 slice block diagram

Capture/Compare Unit 4 (CCU4)

Each CCU4 slice, with the exception of the first, contains six dedicated inputs outputs that are used for the built-in timer concatenation functionality.

Inputs and outputs that are not seen at the CCU4 boundaries have a nomenclature of CC4y.<name>, whilst CCU4 module inputs and outputs are described as CCU4x.<signal_name>y (indicating the variable y the object slice).

Table 17-3 CCU4 slice pin description

| Pin | I/O | Description |
|-----------------|-----|--|
| CCU4x.MCLK | I | Module clock |
| CC4y.TCLK[15:0] | I | Clocks from the pre scaler |
| CCU4x.INy[P:A] | I | Slice functional inputs (used to control the functionality throughout slice external events) |
| CCU4x.MCIy | I | Multi Channel mode input |
| CCU4x.MCSS | I | Multi Channel shadow transfer trigger |
| CC4y.SR[3...0] | O | Slice service request lines |
| CC4x.STy | O | Slice comparison status value |
| CCU4x.PSy | O | Multi channel pattern update trigger |
| CCU4x.OUTy | O | Slice dedicated output pin |

Note:

- The status bit outputs of the Kernel, CCU4x.STy, are extended for one more kernel clock cycle.*
- The Service Request signals at the output of the kernel are extended for one more kernel clock cycle.*
- The maximum output signal frequency of the CCU4x.STy outputs is module clock divided by 4.*

The slice timer, can count up or down depending on the selected operating mode. A direction flag holds the actual counting direction.

The timer is connected to two stand alone comparators, one for the period match and one for a compare match. The registers used for period match and comparison match can be programmed to serve as capture registers enabling sequential capture capabilities on external events.

In normal edge aligned counting scheme, the counter is cleared to 0000_H each time that matches the period value defined in the period register. In center aligned mode, the counter direction changes from 'up counting' to 'down counting' after reaching the period

Capture/Compare Unit 4 (CCU4)

value. Both period and compare registers have an aggregated shadow register, which enables the update of the PWM period and duty cycle on the fly.

A single shot mode is also available, where the counter stops after it reaches the value set in the period register.

The start and stop of the counter can be controlled via software access or by a programmable input pin.

Functions like, load, counting direction (up/down), TRAP and output modulation can also be controlled with external events, see [Section 17.2.3](#).

17.2.2 Input Selector

The first unit of the slice input path, is used to select which inputs are used to control the available external functions.

Inside this block the user also has the possibility to perform a low pass filtering of the signals and selecting the active edge(s) or level of the external event, see [Figure 17-3](#).

Figure 17-3 Slice input selector diagram

The user has the possibility of selecting any of the CCU4x.INy[P:A] inputs as the source of an event.

At the output of this unit we have a user selection of three events, that were configured to be active at rising, falling or both edges, or level active. These selected events can then be mapped to several functions.

Notice that each decoded event contains two outputs, one edge active and one level active, due to the fact that some functions like counting, capture or load are edge sensitive events while, timer gating or up down counting selection are level active.

17.2.3 Connection Matrix

The connection matrix maps the events coming from the input selector to several user configured functions, [Figure 17-4](#). The following functions can be enabled on the connection matrix:

Table 17-4 Connection matrix available functions

| Function | Brief description | Map to figure Figure 17-4 |
|---------------------|---|--|
| Start | Edge signal to start the timer | CCystrt |
| Stop | Edge signal to stop the timer | CCystp |
| Count | Edge signal used for counting events | CCycnt |
| Up/down | Level signal used to select up or down counting direction | CCyupd |
| Capture 0 | Edge signal that triggers a capture into the capture registers 0 and 1 | CCycapt0 |
| Capture 1 | Edge signal that triggers a capture into the capture register 2 and 3 | CCycapt1 |
| Gate | Level signal used to gate the timer clock | CCygate |
| Load | Edge signal that loads the timer with the value present at the compare register | CCyload |
| TRAP | Level signal used for fail-safe operation | CCytrap |
| Modulation | Level signal used to modulate/clear the output | CCymod |
| Status bit override | Status bit is going to be overridden with an input value | CCyoval for the value CCyoset for the trigger |

Inside the connection matrix we also have a unit that performs the built-in timer concatenation. This concatenation enables a completely synchronized operation between the concatenated slices for timing operations and also for capture and load actions. The timer slice concatenation is done via the [CC4yCMC.TCE](#) bitfield. For a complete description of the concatenation function, please address [Section 17.2.9](#).

17.2.4 Starting/Stopping the Timer

Each timer slice contains a run bit register that indicates the actual status of the timer, **CC4yTCST.TRB**. The start and stop of the timer can be done via software access or can be controlled directly by external events, see [Figure 17-5](#).

Selecting an external signal that acts as a start trigger does not force the user to use an external stop trigger and vice versa.

Selecting the single shot mode, imposes that after the counter reaches the period value the run bit, **CC4yTCST.TRB**, is going to be cleared and therefore the timer is stopped.

Figure 17-5 Timer start/stop control diagram

One can use the external stop signal to perform the following functions (configuration via **CC4yTC.ENDM**):

- Clear the run bit (stops the timer) - default
- Clear the timer (to 0000_H) but it does not clear the run bit (timer still running)
- Clear the timer and the run bit

One can use the external start to perform the following functions (configuration via **CC4yTC.STRM**):

- Start the timer (resume operation)
- Clear and start the timer

The set (start the timer) of the timer run bit, always has priority over a clear (stop the timer).

Capture/Compare Unit 4 (CCU4)

To start multiple CCU4 timers at the same time/synchronously one should use a dedicated input as external start (see [Section 17.2.7.1](#) for a description how to configure an input as start function). This input should be connected to all the Timers that need to be started synchronously (see [Section 17.8](#) for a complete list of module connections), [Figure 17-6](#).

For starting the timers synchronously via software there is a dedicated input signal, controlled by the SCU (System Control Unit), that is connected to all the CCU4 timers. This signal should then be configured as an external start signal (see [Section 17.2.7.1](#)) and then the software must write a $1_B/0_B$ (depending on the external start signal configuration) to the specific bitfield of the CCUCON register (this register is described on the SCU chapter).

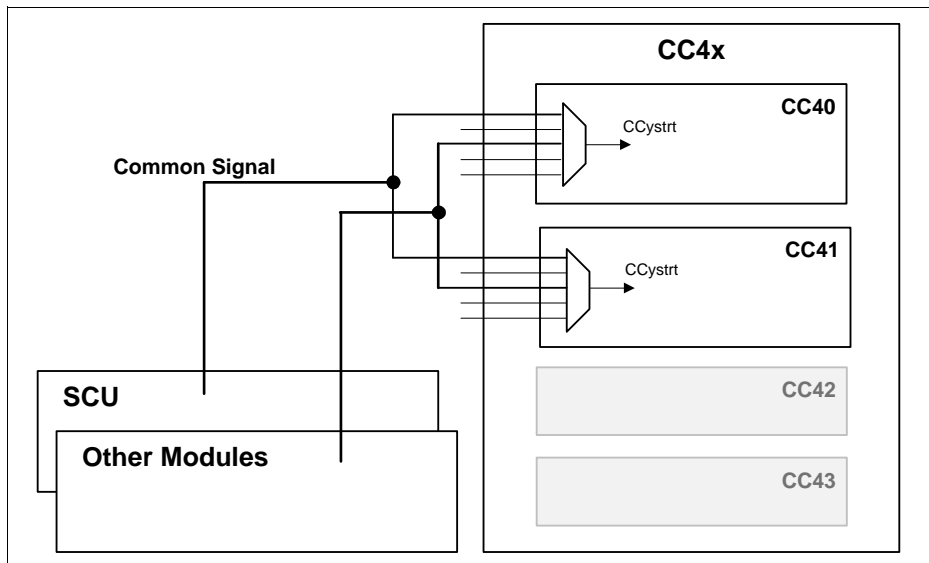

Figure 17-6 Starting multiple timers synchronously

17.2.5 Counting Modes

Each CC4y timer slice can be programmed into three different counting schemes:

- Edge aligned (default)
- Center aligned
- Single shot (can be edge or center aligned)

These three counting schemes can be used as stand alone without the need of selecting any inputs as external event sources. Nevertheless it is also possible to control the

Capture/Compare Unit 4 (CCU4)

counting operation via external events like, timer gating, counting trigger, external stop, external start, etc.

For all the counting modes, it is possible to update on the fly the values for the timer period and compare channel. This enables a cycle by cycle update of the PWM frequency and duty cycle.

The compare channel of each CC4y Timer Slice, has an associated Status Bit (**GCST.CC4yST**), that indicates the active or passive state of the channel, **Figure 17-7**. The set and clear of the status bit and the respective PWM signal generation is dictated by the timer period, compare value and the current counting mode. See the different counting mode descriptions, **Section 17.2.5.3** to **Section 17.2.5.5** to understand how this bit is set and cleared.

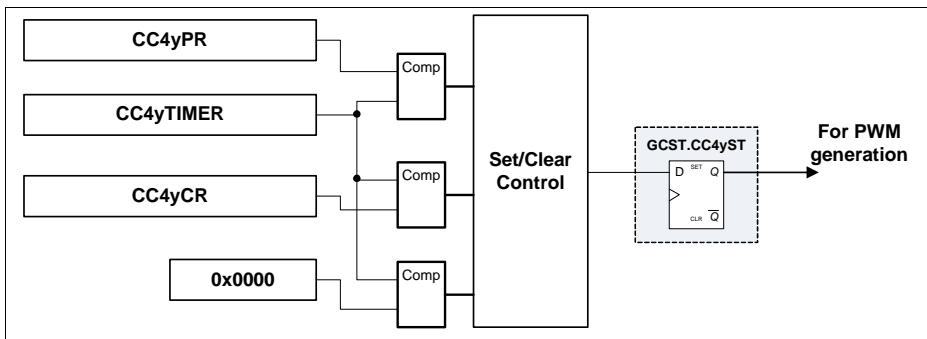

Figure 17-7 CC4y Status Bit

17.2.5.1 Calculating the PWM Period and Duty Cycle

The period of the timer is determined by the value in the period register, **CC4yPR** and by the timer mode.

The base for the PWM signal frequency and duty cycle, is always related to the clock frequency of the timer itself and not to the frequency of the module clock (due to the fact that the timer clock can be a scaled version of the module clock).

In Edge Aligned Mode, the timer period is:

$$T_{\text{per}} = \text{<Period-Value>} + 1; \text{ in } f_{\text{tclk}} \quad (17.1)$$

In Center Aligned Mode, the timer period is:

$$T_{\text{per}} = (\text{<Period-Value>} + 1) \times 2; \text{ in } f_{\text{tclk}} \quad (17.2)$$

For each of these counting schemes, the duty cycle of generated PWM signal is dictated by the value programmed into the **CC4yCR** register.

Capture/Compare Unit 4 (CCU4)

In Edge Aligned and Center Aligned Mode, the PWM duty cycle is:

$$DC = 1 - \frac{\text{Compare-Value}}{(\text{Period-Value} + 1)} \quad (17.3)$$

Both **CC4yPR** and **CC4yCR** can be updated on the fly via software, enabling a glitch free transition between different period and duty cycle values for the generated PWM signal, **Section 17.2.5.2**

17.2.5.2 Updating the Period and Duty Cycle

Each CCU4 timer slice provides an associated shadow register for the period and compare values. This facilitates a concurrent update by software for these two parameters, with the objective of modifying during run time the PWM signal period and duty cycle.

In addition to the shadow registers for the period and compare values, one also has available shadow registers for the floating prescaler and dither functions, **CC4yFPCS** and **CC4yDITS** respectively (please address **Section 17.2.11** and **Section 17.2.10** for a complete description of these functions).

The structure of the shadow registers can be seen in **Figure 17-8**.

Capture/Compare Unit 4 (CCU4)

Figure 17-8 Shadow registers overview

The update of these registers can only be done by writing a new value into the associated shadow register and wait for a shadow transfer to occur.

Each group of shadow registers have an individual shadow transfer enable bit, [Figure 17-9](#). The software must set this enable bit to 1_B, whenever an update of the values is needed. These bits are automatically cleared by the hardware, whenever an update of the values is finished. Therefore every time that an update of the registers is needed the software must set again the specific bit(s).

Nevertheless it is also possible to clear the enable bit via software. This can be used in the case that an update of the values needs to be cancelled (after the enable bit has already been set).

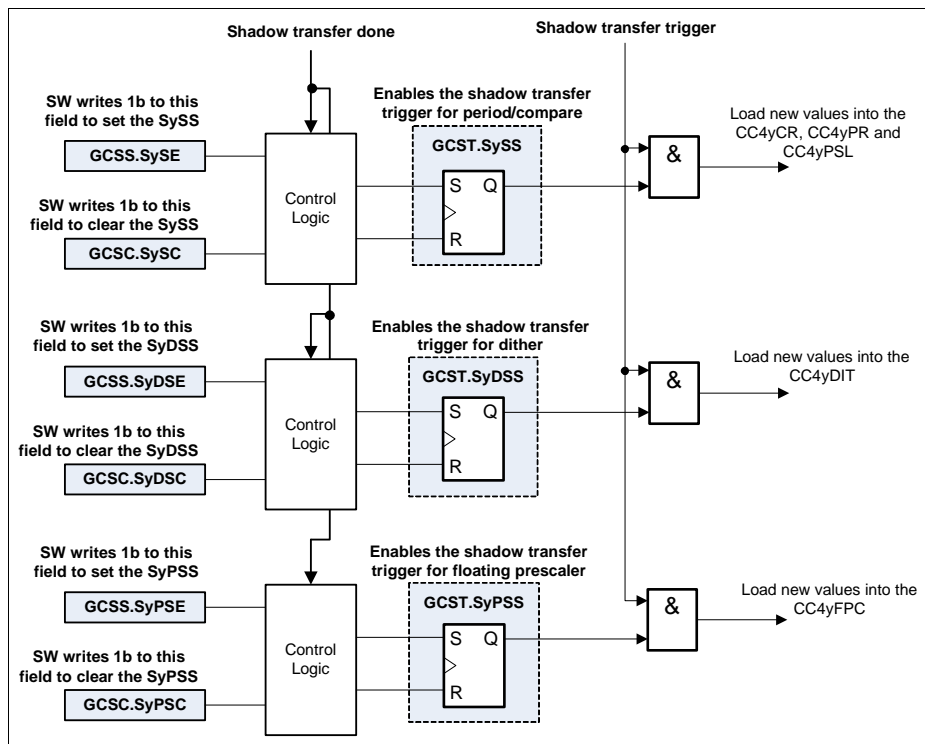

Figure 17-9 Shadow transfer enable logic

The shadow transfer operation is going to be done in the immediately next occurrence of a shadow transfer trigger, after the shadow transfer enable is set (**GCST.SySS**, **GCST.SyDSS**, **GCST.SyPSS** set to 1_B).

The occurrence of the shadow transfer trigger is imposed by the timer counting scheme (edge aligned or center aligned). Therefore the slots when the values are updated can be:

- in the next clock cycle after a Period Match while counting up
- in the next clock cycle after an One Match while counting down
- immediately, if the timer is stopped and the shadow transfer enable bit(s) is set

Figure 17-10 shows an example of the shadow transfer control when the timer slice has been configured into center aligned mode. For a complete description of all the timer slice counting modes, please address [Section 17.2.5.3](#), [Section 17.2.5.4](#) and [Section 17.2.5.5](#).

Figure 17-10 Shadow transfer timing example - center aligned mode

In some application cases it may be necessary to request shadow transfers not by software but by hardware. To perform this action each CCU4 contains a dedicated input that can be used to request a shadow transfer by hardware, the CCU4x.MCSS.

This input, when enabled, is used to set the shadow transfer enable bitfields (**GCST.SySS**, **GCST.SyDSS** and **GCST.SyPSS**) of the specific slice. It is possible to select which slice is using this input to perform the synchronization via the **GCTRL.MSEy** bit field. It is also possible to enable the usage of this signal for the three different shadow transfer signals: compare and period values, dither compare value and prescaler compare value. This can be configured on the **GCTRL.MSDE** field.

The structure for using the CCU4x.MCSS input signal can be seen in **Figure 17-9**. The usage of this signal is just an add on to the shadow transfer control and therefore all the previous described functions are still available.

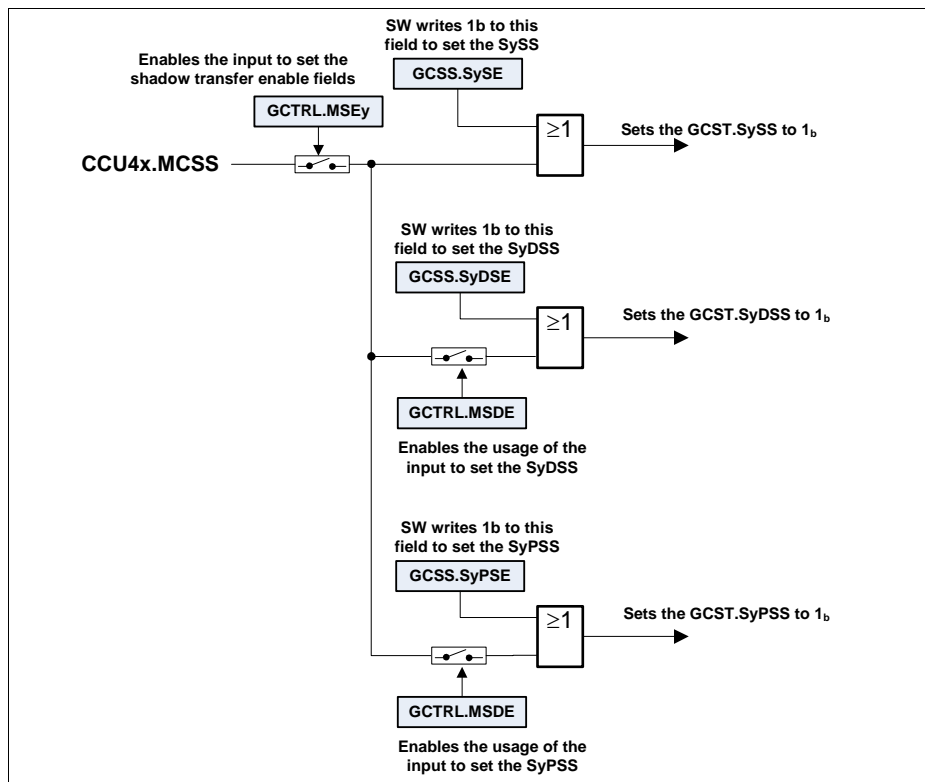

Figure 17-11 Usage of the CCU4x.MCSS input

17.2.5.3 Edge Aligned Mode

Edge aligned mode is the default counting scheme. In this mode, the timer is incremented until it matches the value programmed in the period register, **CC4yPR**. When period match is detected the timer is cleared to 0000_H and continues to be incremented.

In this mode, the value of the period register and compare register are updated with the value written by software into the correspondent shadow register, every time that an overflow occurs (period match), see **Figure 17-12**.

In edge aligned mode, the status bit of the comparison (CC4yST) is set one clock cycle after the timer hits the value programmed into the compare register. The clear of the status bit is done one clock cycle after the timer reaches 0000_H.

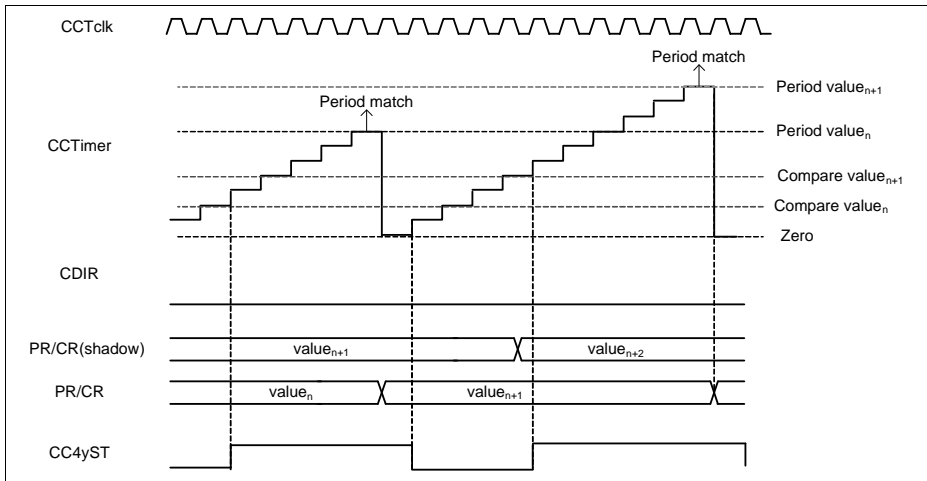

Figure 17-12 Edge aligned mode, **CC4yTCM = 0_B**

17.2.5.4 Center Aligned Mode

In center aligned mode, the timer is counting up or down with respect to the following rules:

- The counter counts up while **CC4yTCST.CDIR** = 0_B and it counts down while **CC4yTCST.CDIR** = 1_B.
- Within the next clock cycle, the count direction is set to counting up (**CC4yTCST.CDIR** = 0_B) when the counter reaches 0001_H while counting down.
- Within the next clock cycle, the count direction is set to counting down (**CC4yTCST.CDIR** = 1_B), when the period match is detected while counting up.

The status bit (CC4yST) is always 1_B when the counter value is equal or greater than the compare value and 0_B otherwise.

While in edge aligned mode, the shadow transfer for compare and period registers is executed once per period. It is executed twice in center aligned mode as follows

- Within the next clock cycle after the counter reaches the period value, while counting up (**CC4yTCST.CDIR** = 0_B).
- Within the next clock cycle after the counter reaches 0001_H, while counting down (**CC4yTCST.CDIR** = 1_B).

*Note: Bit **CC4yTCST.CDIR** changes within the next timer clock after the one-match or the period-match, which means that the timer continues counting in the previous direction for one more cycle before changing the direction.*

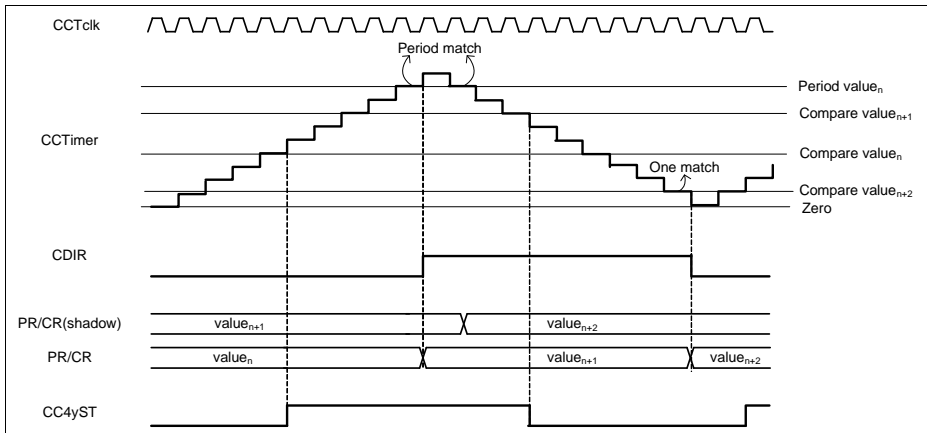

Figure 17-13 Center aligned mode, $CC4yTC.TCM = 1_B$

17.2.5.5 Single Shot Mode

In single shot mode, the timer is stopped after the current timer period is finished. This mode can be used with center or edge aligned scheme.

In edge aligned mode, **Figure 17-14**, the timer is stopped when it is cleared to 0000_H after having reached the period value. In center aligned mode, **Figure 17-15**, the period is finished when the timer has counted down to 0000_H.

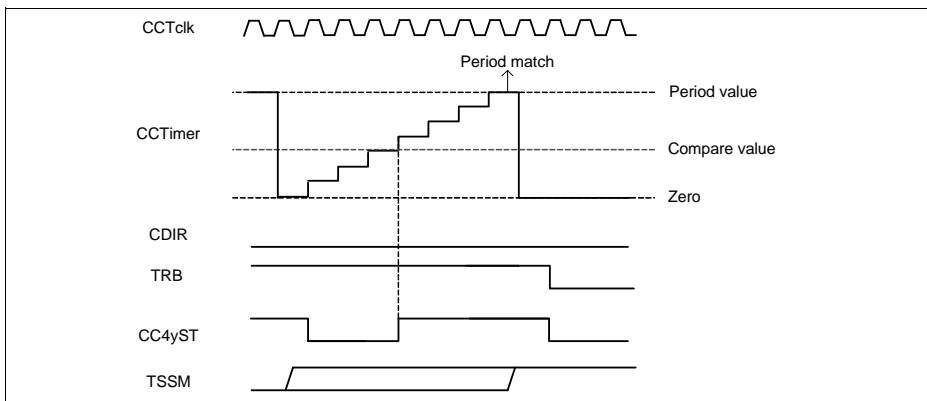

Figure 17-14 Single shot edge aligned - $CC4yTC.TSSM = 1_B$, $CC4yTC.TCM = 0_B$

Figure 17-15 Single shot center aligned - $CC4yTC.TSSM = 1_B$, $CC4yTC.TCM = 1_B$

17.2.6 Active/Passive Rules

The general rules that set or clear the associated timer slice status bit (CC4yST), can be generalized independently of the timer counting mode.

The following events set the Status bit (CC4yST) to Active:

- in the next f_{tclk} cycle after a compare match while counting up
- in the next f_{tclk} cycle after a zero match while counting down

The following events set the Status bit (CC4yST) to Inactive:

- in the next f_{tclk} cycle after a zero match (and not compare match) while counting up
- in the next f_{tclk} cycle after a compare match while counting down

If external events are being used to control the timer operation, these rules are still applicable.

The status bit state can only be 'override' via software or by the external status bit override function, [Section 17.2.7.10](#).

The software can at any time write a 1_B into the [GCSS.SySTS](#) bitfield, which will set the status bit [GCST.CC4yST](#) of the specific timer slice. Writing a 1_B into the [GCSC.SySTC](#) bitfield will clear the specific status bit.

17.2.7 External Events Control

Each CCU4 timer slice has the possibility of using up to three different input events, see [Section 17.2.2](#). These three events can then be mapped to Timer Slice functions (the full set of available functions is described at [Section 17.2.3](#))

These events can be mapped to any of the CCU4x.INy[P...A] inputs and there isn't any imposition that an event cannot be used to perform several functions, or that an input

cannot be mapped to several events (e.g. input X triggers event 0 with rising edge and triggers event 1 with the falling edge).

17.2.7.1 External Start/Stop

To select an external start function, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** field and indicating the active edge of the signal on the **CC4yINS.EVxEM** field.

This event should be then mapped to the start or stop functionality by setting the **CC4yCMC.STRTS** (for the start) or the **CC4yTC.ENDM** (for the stop) with the proper value.

Notice that both start and stop functions are edge and not level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

The external stop by default just clears the run bit (**CC4yTCST.TRB**), while the start functions does the opposite. Nevertheless one can select an extended subset of functions for the external start and stop. This subset is controlled by the registers **CC4yTC.ENDM** (for the stop) and **CC4yTC.STRM** (for the start).

For the start subset (**CC4yTC.STRM**):

- sets the run bit/starts the timer (resume operation)
- clears the timer, sets the run bit/starts the timer (flush and start)

For the stop subset (**CC4yTC.ENDM**):

- clears the run/stops the timer (stop)
- clears the timer (flush)
- clears the timer, clears the run bit/stops the timer (flush and stop)

If in conjunction with an external start/stop (configured also/only as flush) and external up/down signal is used, during the flush operation the timer is going to be set to 0000_H if the actual counting direction is up or set with the value of the period register if the counting direction is down.

Figure 17-16 to **Figure 17-19** shows the usage of two signals to perform the start/stop functions in all the previously mentioned subsets. External Signal(1) acts as an active HIGH start signal, while External Signal(2) is used as an active HIGH stop function.

Capture/Compare Unit 4 (CCU4)

**Figure 17-18 Start (as flush and start)/ stop (as stop) - $CC4yTC.STRM = 1_B$,
 $CC4yTC.ENDM = 00_B$**

**Figure 17-19 Start (as start)/ stop (as flush and stop) - $CC4yTC.STRM = 0_B$,
 $CC4yTC.ENDM = 10_B$**

17.2.7.2 External Counting Direction

There is the possibility of selecting an input signal to act as increment/decrement control. To select an external up/down control, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the $CC4yINS.EVxIS$ field and indicating the active level of the signal on the $CC4yINS.EVxLM$. This event should be then mapped to the up/down functionality by setting $CC4yCMC.UDS$ with the proper value.

Capture/Compare Unit 4 (CCU4)

Notice that the up/down function is level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxLM**.

The status bit of the slice (**CC4yST**) is always set when the timer value is equal or greater than the value stored in the compare register, see [Section 17.2.6](#).

The update of the period and compare register values is done when:

- with the next clock after a period match, while counting up (**CC4yTCST.CDIR** = 0_B)
- with the next clock after a one match, while counting down (**CC4yTCST.CDIR** = 1_B)

The value of the **CC4yTCST.CDIR** register is updated accordingly with the changes on the decoded event. The Up/Down direction is always understood as **CC4yTCST.CDIR** = 1_B when counting down and **CC4yTCST.CDIR** = 0_B when counting up. Using an external signal to perform the up/down counting function and configuring the event as active HIGH means that the timer is counting up when the signal is HIGH and counting down when LOW.

Figure 17-20 shows an external signal being used to control the counting direction of the time. This signal was selected as active HIGH, which means that the timer is counting down while the signal is HIGH and counting up when the signal is LOW.

*Note: For a signal that should impose an increment when LOW and a decrement when HIGH, the user needs to set the **CC4yINS.EVxLM** = 0_B. When the operation is switched, then the user should set **CC4yINS.EVxLM** = 1_B.*

Note: Using an external counting direction control, sets the slice in edge aligned mode.

Figure 17-20 External counting direction

17.2.7.3 External Gating Signal

For pulse measurement, the user has the possibility of selecting an input signal that operates as counting gating.

To select an external gating control, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active level of the signal on the **CC4yINS.EVxLM** register. This event should be then mapped to the gating functionality by setting the **CC4yCMC.GATES** with the proper value.

Notice that the gating function is level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxLM**.

The status bit during an external gating signal continues to be asserted when the compare value is reached and deasserted when the counter reaches 0000_H. One should note that the counter continues to use the period register to identify the wrap around condition. **Figure 17-21** shows the usage of an external signal for gating the slice counter. The signal was set as active LOW, which means the counter gating functionality is active when the external value is zero.

Figure 17-21 External gating

For any type of usage of the external gating function, the specific run bit of the Timer Slice, **CC4yTCST.TRB**, needs to be set. This can be done via an additional external signal or directly via software.

17.2.7.4 External Count Signal

There is also the possibility of selecting an external signal to act as the counting event.

To select an external counting, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active edge of the signal on the **CC4yINS.EVxEM** register.

Capture/Compare Unit 4 (CCU4)

This event should be then mapped to the counting functionality by setting the **CC4yCMC.CNTS** with the proper value.

Notice that the counting function is edge active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

One can select just a the rising, falling or both edges to perform a count. On **Figure 17-22**, the external signal was selected as a counter event for both falling and rising edges. Wrap around condition is still applied with a comparison with the period register.

Figure 17-22 External count

For any type of usage of the external gating function, the specific run bit of the Timer Slice, **CC4yTCST.TRB**, needs to be set. This can be done via an additional external signal or directly via software.

17.2.7.5 External Load

Each slice of the CCU4 also has a functionality that enables the user to select an external signal as trigger for reloading the value of the timer with the current value of the compare register (if **CC4yTCST.CDIR** = 0_B) or with the value of the period register (if **CC4yTCST.CDIR** = 1_B).

To select an external load signal, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active edge of the signal on the **CC4yINS.EVxEM** register. This event should be then mapped to the load functionality by setting the **CC4yCMC.LDS** with the proper value.

Notice that the load function is edge active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

On figure **Figure 17-23**, the external signal (1) was used to act as a load trigger, active on the rising edge. Every time that a rising edge on external signal (1) is detected, the

Capture/Compare Unit 4 (CCU4)

timer value is loaded with the value present on the compare register. If an external signal is being used to control the counting direction, up or down, the timer value can be loaded also with the value set in the period register. The External signal (2) represents the counting direction control (active HIGH). If at the moment that a load trigger is detected, the signal controlling the counting direction is imposing a decrement, then the value set in the timer is the period value.

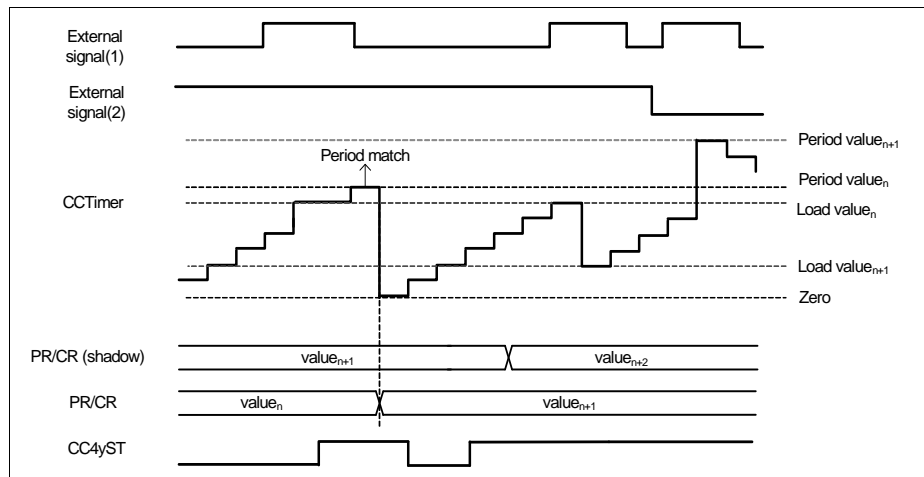

Figure 17-23 External load

17.2.7.6 External Capture

When selecting an external signal to be used as a capture trigger (if **CC4yCMC.CAP0S** or **CC4yCMC.CAP1S** are different from 0_H), the user is automatically setting the specific slice into capture mode.

In capture mode the user can have up to four capture registers, see **Figure 17-26**: capture register 0 (**CC4yC0V**), capture register 1 (**CC4yC1V**), capture register 2 (**CC4yC2V**) and capture register 3 (**CC4yC3V**).

These registers are shared between compare and capture modes which imposes:

- if **CC4yC0V** and **CC4yC1V** are used for capturing, the compare registers **CC4yCR** and **CC4yCRS** are not available (no compare channel)
- if **CC4yC2V** and **CC4yC3V** are used for capturing, the period registers **CC4yPR** and **CC4yPRS** are not available (no period control)

To select an external capture signal, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active edge of the signal on the

Capture/Compare Unit 4 (CCU4)

CC4yINS.EVxEM register. This event should be then mapped to the capture functionality by setting the **CC4yCMC.CAP0S/CC4yCMC.CAP1S** with the proper value.

Notice that the capture function is edge active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

The user has the possibility of selecting the following capture schemes:

- Different capture events for **CC4yC0V/CC4yC1V** and **CC4yC2V/CC4yC3V**
- The same capture event for **CC4yC0V/CC4yC1V** and **CC4yC2V/CC4yC3V** with the same capture edge. For this capture scheme, only the CCcap1 functionality needs to be programmed. To enable this scheme, the field **CC4yTC.SCE** needs to be set to 1.

Different Capture Events (SCE = 0_B)

Every time that a capture trigger 1 occurs, CCcap1, the actual value of the timer is captured into the capture register 3 and the previous value stored in this register is transferred into capture register 2.

Every time that a capture trigger 0 occurs, CCcap0, the actual value of the timer is captured into the capture register 1 and the previous value stored in this register is transferred into capture register 0.

Every time that a capture procedure into one of the registers occurs, the respective full flag is set. This flag is cleared automatically by HW when the SW reads back the value of the capture register (by reading the specific capture register or by reading the extended capture read value, see [Section 17.2.7.7](#)).

The capture of a new value into a specific capture registers is dictated by the status of the full flag as follows:

$$CC4yC1V_{\text{capt}} = \text{NOT}(CC4yC1V_{\text{full_flag}} \text{ AND } CC4yC0V_{\text{full_flag}}) \quad (17.4)$$

$$CC4yC0V_{\text{capt}} = CC4yC1V_{\text{full_flag}} \text{ AND NOT}(CC4yC0V_{\text{full_flag}}) \quad (17.5)$$

It is also possible to disable the effect of the full flags reset by setting the **CC4yTC.CCS** = 1_B. This enables a continuous capturing independent if the values captured have been read or not.

*Note: When using the period registers for capturing, **CC4yCMC.CAP1S** different from 00_B, the counter always uses its full 16 bit width as period value.*

On [Figure 17-24](#), an external signal was selected as an event for capturing the timer value into the **CC4yC0V/CC4yC1V** registers. The status bit, CC4yST, during capture mode is asserted whenever a capture trigger is detected and deasserted when the counter matches 0000_H.

Figure 17-24 External capture - $\text{CC4yCMC.CAP0S} \neq 00_B$, $\text{CC4yCMC.CAP1S} = 00_B$

On [Figure 17-25](#), two different signals were used as source for capturing the timer value into the [CC4yC0V/CC4yC1V](#) and [CC4yC2V/CC4yC3V](#) registers.

External signal(1) was selected as rising edge active capture source for [CC4yC0V/CC4yC1V](#). External signal(2) was selected as the capture source for [CC4yC2V/CC4yC3V](#), but as opposite to the external signal(1), the active edge was selected as falling.

See [Section 17.2.12.4](#), for the complete capture mode usage description.

Capture/Compare Unit 4 (CCU4)

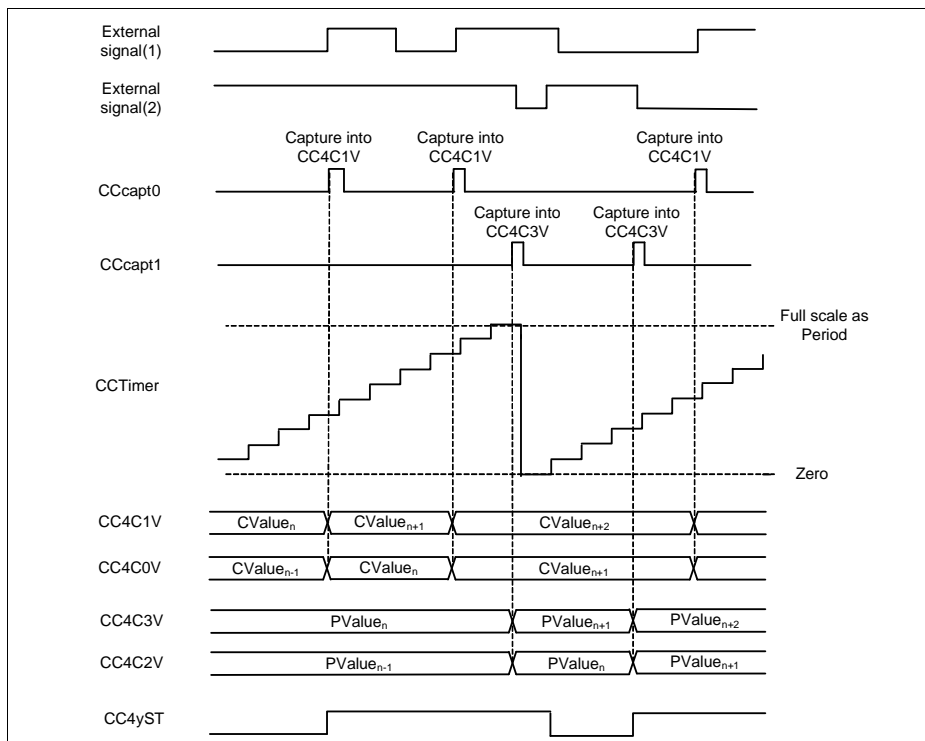

Figure 17-25 External capture - $CC4yCMC.CAP0S \neq 00_B$, $CC4yCMC.CAP1S \neq 00_B$

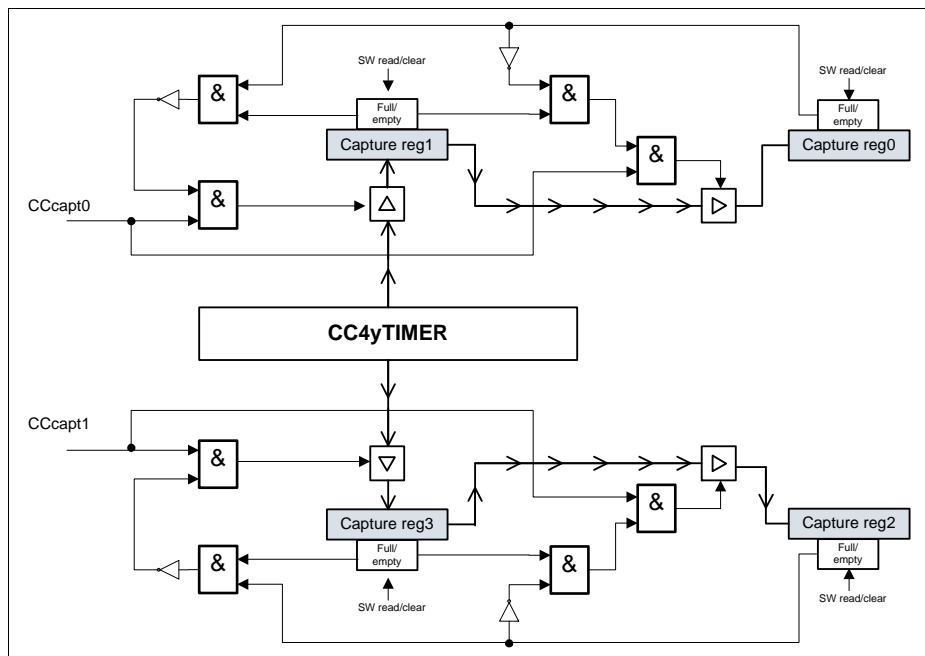

Figure 17-26 Slice capture logic

Same Capture Event (SCE = 1_B)

Setting the field **CC4yTC.SCE = 1_B**, enables the possibility of having 4 capture registers linked with the same capture event, **Figure 17-28**. The function that controls the capture is the **CCCapt1**.

The capture logic follows the same structure shown in **Figure 17-26** but extended to a four register chain, see **Figure 17-27**. The same full flag lock rules are applied to the four register chain (it also can be disabled by setting the **CC4yTC.CCS = 1_B**):

$$CC4yC3V_{capt} = \text{NOT}(CC4yC3V_{full_flag} \text{ AND } CC4yC2V_{full_flag} \text{ AND } CC4yC2V_{full_flag} \text{ AND } CC4yC1V_{full_flag}) \quad (17.6)$$

$$CC4yC2V_{capt} = CC4yC3V_{full_flag} \text{ AND NOT}(CC4yC2V_{full_flag} \text{ AND } CC4yC1V_{full_flag} \text{ AND } CC4yC0V_{full_flag}) \quad (17.7)$$

$$CC4yC1V_{capt} = CC4yC2V_{full_flag} \text{ AND NOT}(CC4yC1V_{full_flag} \text{ AND } CC4yC0V_{full_flag}) \quad (17.8)$$

$$CC4yC0V_{capt} = CC4yC1V_{full_flag} \text{ AND NOT}(CC4yC0V_{full_flag}) \quad (17.9)$$

Capture/Compare Unit 4 (CCU4)

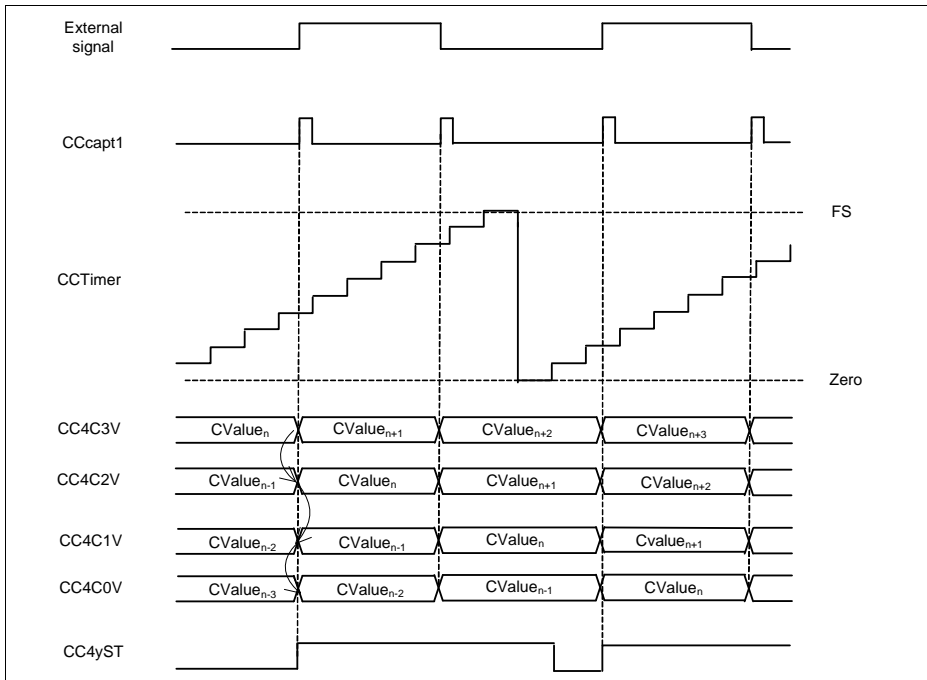

Figure 17-27 External Capture - **CC4yTC.SCE = 1_B**

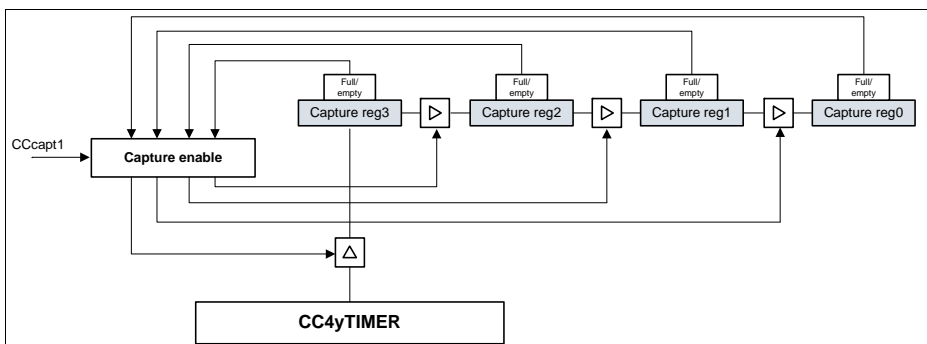

Figure 17-28 Slice Capture Logic - **CC4yTC.SCE = 1_B**

17.2.7.7 Capture Extended Read Back Mode

Each Timer Slice capture logic can operate in a FIFO read back mode. This mode can be enabled by setting the **CC4yTC.ECM** = 1_B. This Extended Read back mode allows the software to read back the capture data always from the same address (**CC4yECRD0** for the structure linked with the capture trigger 0 or **CC4yECRD1** for the one linked with capture trigger 1). This read back will always return the oldest captured value, enabling an easy software routine implementation for reconstructing the capture data.

This function allows the usage of a FIFO structure for each capturing trigger. This relaxes the software read back routine when multiple capture triggers are present, and the software is not fast enough to perform a read operation in each capture event.

This FIFO read back function is present for a depth-4 and depth-2 FIFO structure.

The read back data contains also a lost value bitfield, that indicates if a capture trigger was lost due to the fact that the FIFO structure was full. This bitfield is set whenever a capture event was sensed and the FIFO was full (regardless if the continuous capture mode was enabled or not). This bitfield is cleared automatically by HW whenever the next read of the **CC4yECRD0/CC4yECRD1** register occurs. This bitfield does not indicate how many capture events were lost, it just indicates that between two ECRD reads at least a capture event was lost (this can help the SW evaluate which part of the data read, can be used for calculation).

*Note: When the ECM bitfield is set, reading the individual capture registers is still possible. Nevertheless the full flags can only be cleared by the HW when a read back is done via the **CC4yECRD0/CC4yECRD1** address.*

Depth 4 Structure

The FIFO depth-4 structure is present in the hardware when the capture trigger 1 is enabled and the **CC4yTC.SCE** = 1_B (same capture event), **Figure 17-29**.

Capture/Compare Unit 4 (CCU4)

Figure 17-29 Capture Extended Read Back - Depth 4

Capture/Compare Unit 4 (CCU4)

Figure 17-30 Depth 4 software access example

Depth 2 Structure

Each Timer Slice can have two capture structures of depth-2: one used with capture trigger 0 and another with capture trigger 1.

The one linked with capture trigger 0, is accessed via the **CC4yECRD0** while the one linked with the capture trigger 1 is accessed via the **CC4yECRD1**, [Figure 17-31](#).

Figure 17-31 Capture Extended Read Back - Depth 2

Figure 17-32 Depth 2 software access example

17.2.7.8 External Modulation

An external signal can be used to perform a modulation at the output of each timer slice.

To select an external modulation signal, one should map one of the input signals to one of the events, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active level of the signal on the **CC4yINS.EVxLM** register. This event should be then

Capture/Compare Unit 4 (CCU4)

mapped to the modulation functionality by setting the **CC4yCMC.MOS** = 01_B if event 0 is being used, **CC4yCMC.MOS** = 10_B if event 1 or **CC4yCMC.MOS** = 11_B if event 2.

Notice that the modulation function is level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxLM**.

The modulation has two modes of operation:

- modulation event is used to clear the CC4yST bit - **CC4yTC.EMT** = 0_B
- modulation event is used to gate the outputs - **CC4yTC.EMT** = 1_B

On **Figure 17-33**, we have an external signal configured to act as modulation source that clears the CC4yST bit, **CC4yTC.EMT** = 0_B. It was programmed to be an active LOW event and therefore, when this signal is LOW the output value follows the normal ACTIVE/PASSIVE rules.

When the signal is HIGH (inactive state), then the CC4yST bit is cleared and the output is forced into the PASSIVE state. Notice that the values of the status bit, CC4yST and the specific output CCU4x.OUTy are not linked together. One can choose for the output to be active LOW or HIGH through the PSL bit.

The exit of the external modulation inactive state is synchronized with the PWM signal due to the fact that the CC4yST bit is cleared and cannot be set while the modulation signal is inactive.

The entering into inactive state also can be synchronized with the PWM signal, by setting **CC4yTC.EMS** = 1_B. With this all possible glitches at the output are avoided, see **Figure 17-34**.

Figure 17-33 External modulation clearing the ST bit - **CC4yTC.EMT = 0_B**

Figure 17-34 External modulation clearing the ST bit - $\text{CC4yTC.EMT} = 0_B$,
 $\text{CC4yTC.EMS} = 1_B$

On Figure 17-35, the external modulation event was used as gating signal of the outputs, $\text{CC4yTC.EMT} = 1_B$. The external signal was configured to be active HIGH, $\text{CC4yINS.EVxLM} = 0_B$, which means that when the external signal is HIGH the outputs are set to the PASSIVE state. In this mode, the gating event can also be synchronized with the PWM signal by setting the $\text{CC4yTC.EMS} = 1_B$.

Figure 17-35 External modulation gating the output - $\text{CC4yTC.EMT} = 1_B$

17.2.7.9 TRAP Function

The TRAP functionality allows the PWM outputs to react on the state of an input pin. This functionality can be used to switch off the power devices if the TRAP input becomes active.

To select the TRAP functionality, one should map one of the input signals to event number 2, by setting the required value in the **CC4yINS.EV2IS** register and indicating the active level of the signal on the **CC4yINS.EV2LM** register. This event should be then mapped to the trap functionality by setting the **CC4yCMC.TS = 1_B**.

Notice that the trap function is level active and therefore the active/passive configuration is set only by the **CC4yINTS.EV2LM**.

There are two bitfields that can be monitored via software to crosscheck the TRAP function, **Figure 17-36**:

- The TRAP state bit, **CC4yINTS.E2AS**. This bitfield is the TRAP is currently active or not. This bitfield is therefore setting the specific Timer Slice output, into ACTIVE or PASSIVE state.
- The TRAP Flag, **CC4yINTS.TRPF**. This bitfield is used as a remainder in the case that the TRAP condition is cleared automatically via hardware. This field needs to be cleared by the software.

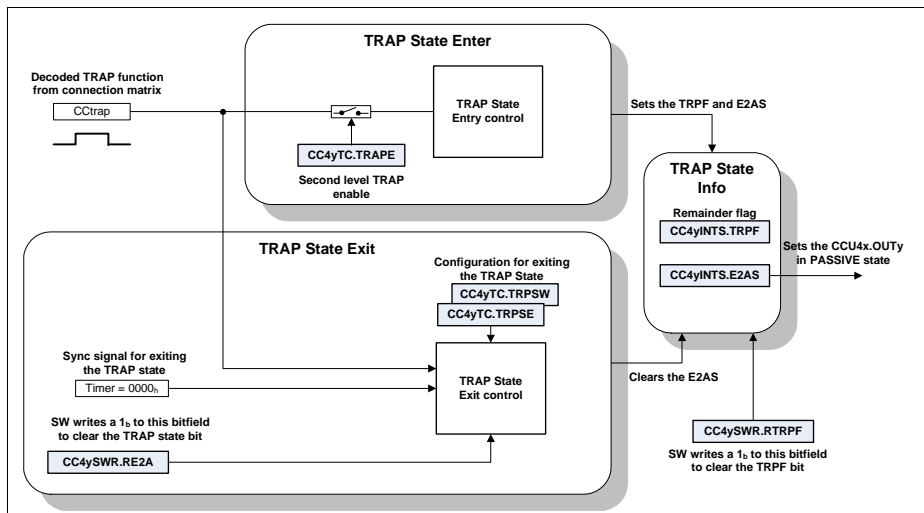

Figure 17-36 Trap control diagram

When a TRAP condition is detected at the selected input pin, both the Trap Flag and the Trap State bit are set to 1_B. The Trap State is entered immediately, by setting the CCU4xOUTy into the programmed PASSIVE state, **Figure 17-37**.

Capture/Compare Unit 4 (CCU4)

Exiting the Trap State can be done in two ways (**CC4yTC**.TRPSW register):

- automatically via HW, when the TRAP signal becomes inactive - **CC4yTC**.TRPSW = 0_B
- by SW only, by clearing the **CC4yINTS**.E2AS. The clearing is only possible if the input TRAP signal is in inactive state - **CC4yTC**.TRPSW = 1_B

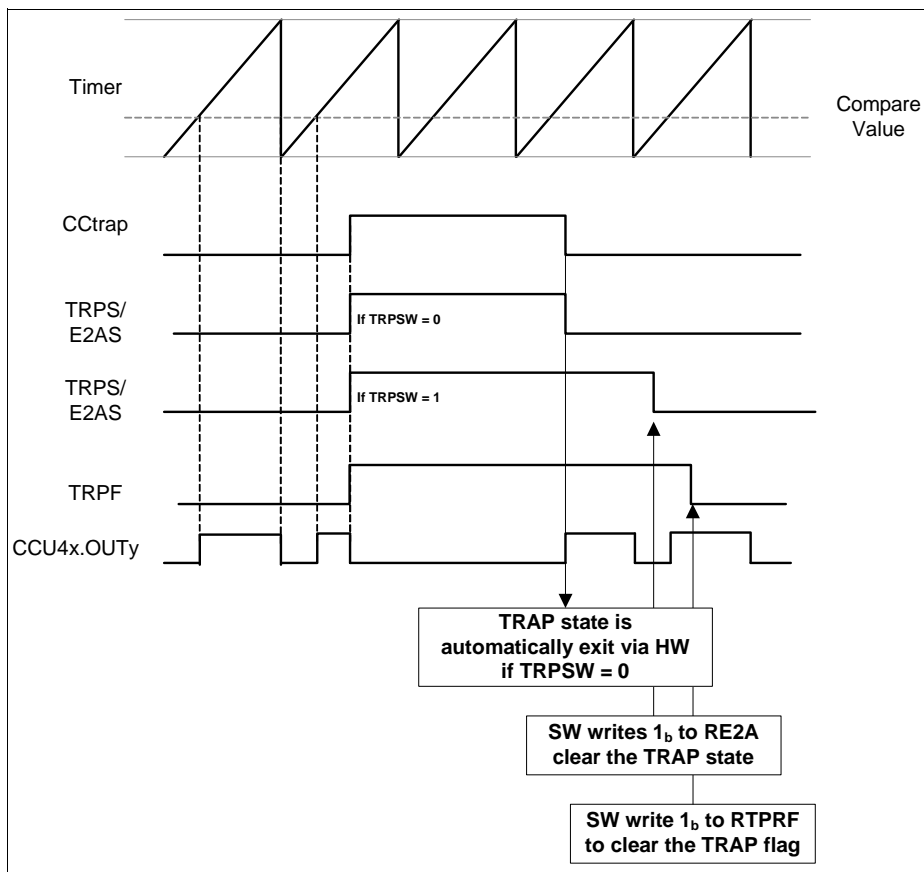

Figure 17-37 Trap timing diagram, **CC4yPSL**.PSL = 0_B (output passive level is 0_B)

It is also possible to synchronize the exiting of the TRAP state with the PWM signal, **Figure 17-38**. This function is enabled when the bitfield **CC4yTC**.TRPSE = 1_B .

Figure 17-38 Trap synchronization with the PWM signal, **CC4yTC.TRPSE = 1_B**

17.2.7.10 Status Bit Override

For complex timed output control, each Timer Slice has a functionality that enables the override of the status bit (CC4yST) with a value passed through an external signal.

The override of the status bit, can then lead to a change on the output pin, CCU4xOUTy (from inactive to active or vice versa).

To enable this functionality, two signals are needed:

- One signal that acts as a trigger to override the status bit (edge active)
- One signal that contains the value to be set in the status bit (level active)

To use the status bit override functionality, one should map the signal that acts as trigger to the event number 1, by setting the required value in the **CC4yINS.EV1IS** register and indicating the active edge of the signal on the **CC4yINS.EV1EM** register.

The signal that carries the value to be set on the status bit, needs to be mapped to the event number 2, by setting the required value in the **CC4yINS.EV2IS** register. The **CC4yINS.EV2LM** register should be set to 0_B if no inversion on the signal is needed and to 1_B otherwise.

The events should be then mapped to the status bit functionality by setting the **CC4yCMC.OFS = 1_B**.

Figure 17-39 shows the functionality of the status bit override, when the external signal(1) was selected as trigger source (rising edge active) and the external signal(2) was selected as override value.

Figure 17-39 Status bit override

17.2.8 Multi-Channel Control

The multi channel control mode is selected individually in each slice by setting the **CC4yTC.MCME** = 1_B.

Within this mode, the output state of the Timer Slices (the ones set in multi channel mode) can be controlled in parallel by a single pattern.

The pattern is controlled via the CCU4 inputs, CCU4x.MCI0, CCU4x.MCI1, CCU4x.MCI2 and CCU4x.MCI3. Each of these inputs is connected directly to the associated slice input, e.g. CCU4x.MCI0 to CC40MCI, CCU4x.MCI1 to CC41MCI.

This pattern can be controlled directly by other module. The connectivity of each device may allow different control possibilities therefore one should address [Section 17.8](#) to check what modules are connected to these inputs.

When using the Multi Channel support of the CCU4, one can achieve a complete synchronicity between the output state update, CCU4x.OUTy, and the update of a new pattern, [Figure 17-40](#). This synchronicity feature can be enabled by using some specific modules and therefore one should address [Section 17.8](#) to check which module is controlling the CCU4x.MCIy inputs.

Figure 17-40 Multi channel pattern synchronization

Figure 17-41 shows the usage of the multi channel mode in conjunction with all four Timer Slices inside the CCU4.

Figure 17-41 Multi Channel mode for multiple Timer Slices

The synchronization between the CCU4 and the module controlling the multi-channel pattern is achieved, by adding a 3 cycle delay on the output path of each Timer Slice

Capture/Compare Unit 4 (CCU4)

(between the status bit, CC4yST and the direct control of the output pin). This path is only selected when **CC4yTC.MCME** = 1_B, see **Figure 17-42**.

The multi pattern input synchronization can be seen on **Figure 17-43**. To achieve a synchronization between the update of the status bit, the sampling of a new multi channel pattern input is controlled by the period match or one match signal.

In a straightforward utilization of this synchronization feature, the module controlling the multi channel pattern signals, receives a sync signal from the CCU4, the CCU4x.PSy. This signal is then used by this module to update the multi-channel pattern. Due to the structure of the synchronization scheme inside the CCU4, the module controlling the multi-channel pattern needs to update this pattern, within 4 clock cycles after the CCU4x.PSy signal is asserted, **Figure 17-43**.

In a normal operation, where no external signal is used to control the counting direction, the signal used to enable the sampling of the pattern is always the period match when in edge aligned and the one match when in center aligned mode. When an external signal is used to control the counting direction, depending if the counter is counting up or counting down, the period match or the one match signal is used, respectively.

Figure 17-42 CC4y Status bit and Output Path

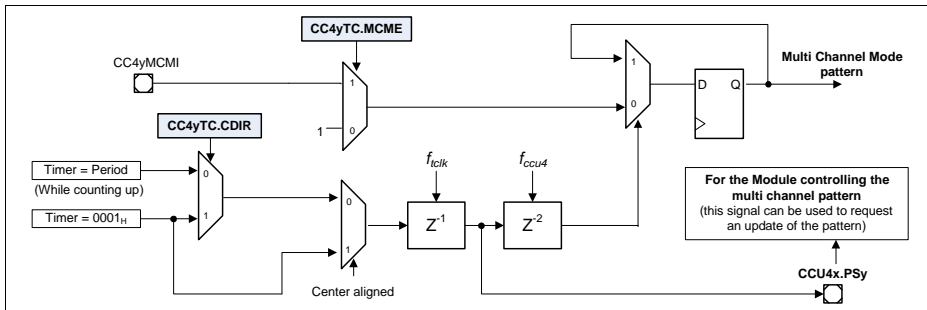

Figure 17-43 Multi Channel Mode Control Logic

17.2.9 Timer Concatenation

The CCU4 offers a very easy mechanism to perform a synchronous timer concatenation. This functionality can be used by setting the **CC4yCMC.TCE** = 1_B . By doing this the user is doing a concatenation of the actual CCU4 slice with the previous one, see [Figure 17-44](#).

Notice that it is not possible to perform concatenation with non adjacent slices and that timer concatenation automatically sets the slice mode into Edge Aligned. It is not possible to perform timer concatenation in Center Aligned mode.

To enable a 64 bit timer, one should set the **CC4yCMC.TCE** = 1_B in all the slices (with the exception of the CC40 due to the fact that it doesn't contain this control register).

To enable a 48 bit timer, one should set the **CC4yCMC.TCE** = 1_B in two adjacent slices and to enable a 32 bit timer, the **CC4yCMC.TCE** is set to 1_B in the slice containing the MSBs. Notice that the timer slice containing the LSBs should always have the TCE bitfield set to 0_B .

Several combinations for timer concatenation can be made inside a CCU4 module:

- one 64 bit timer
- one 48 bit timer plus a 16 timer
- two 32 bit timers
- one 32 bit timer plus two 16 bit timers

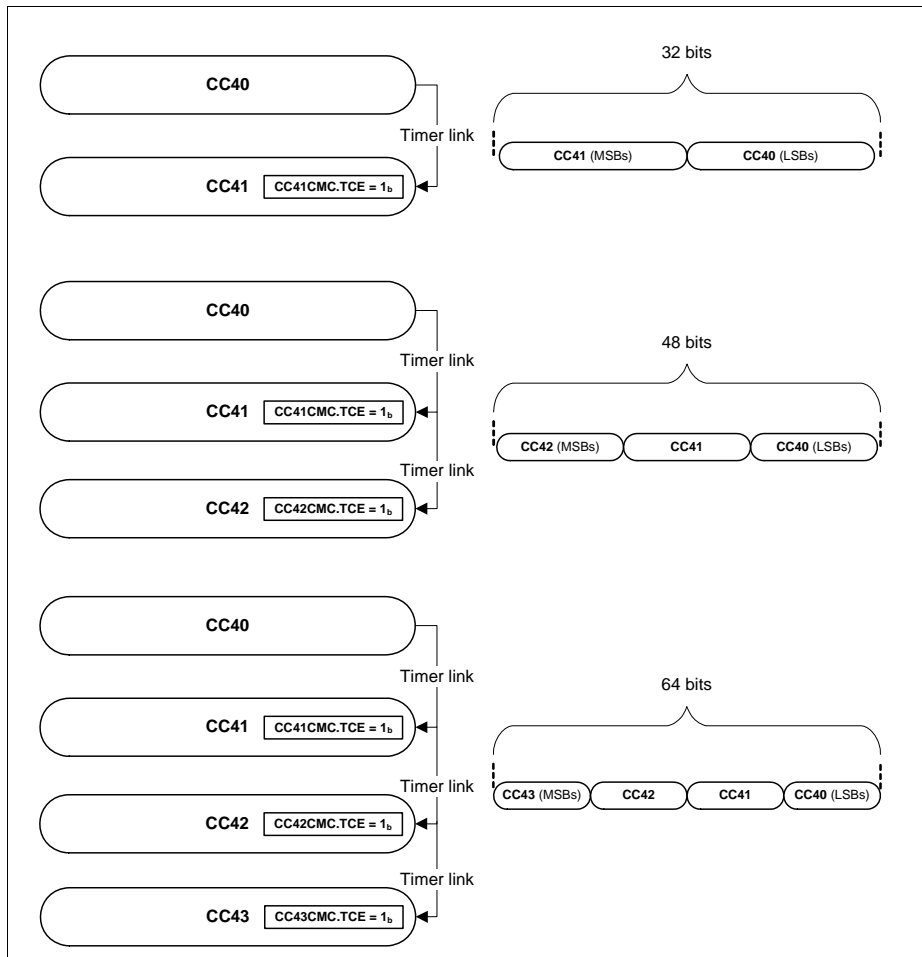

Figure 17-44 Timer Concatenation Example

Each Timer Slice is connected to the adjacent Timer Slices via a dedicated concatenation interface. This interface allows the concatenation of not only the Timer counting operation, but also a synchronous input trigger handling for capturing and loading operations, [Figure 17-45](#).

Note: For all cases CC40 and CC43 are not considered adjacent slices

Figure 17-45 Timer Concatenation Link

Seven signals are present in the timer concatenation interface:

- Timer Period match (CC4yPM)
- Timer Zero match (CC4yZM)
- Timer Compare match (CC4yCM)
- Timer counting direction function (CCupd)
- Timer load function (CCload)
- Timer capture function for CC4yC0V and CC4yC1V registers (CCcap0)
- Timer capture function for CC4yC2V and CC4yC3V registers (CCcap1)

The first four signals are used to perform the synchronous timing concatenation at the output of the Timer Logic, like it is seen in [Figure 17-45](#). With this link, the timer length can be easily adjusted to 32, 48 or 64 bits (counting up or counting down).

The last three signals are used to perform a synchronous link between the capture and load functions, for the concatenated timer system. This means that the user can have a capture or load function programmed in the first Timer Slice, and propagate this capture or load trigger synchronously from the LSBs until the MSBs, [Figure 17-46](#).

The capture or load function only needs to be configured in the first Timer Slice (the one holding the LSBs). From the moment that **CC4yCMC.TCE** is set to 1_B, in the following Timer Slices, the link between these functions is done automatically by the hardware.

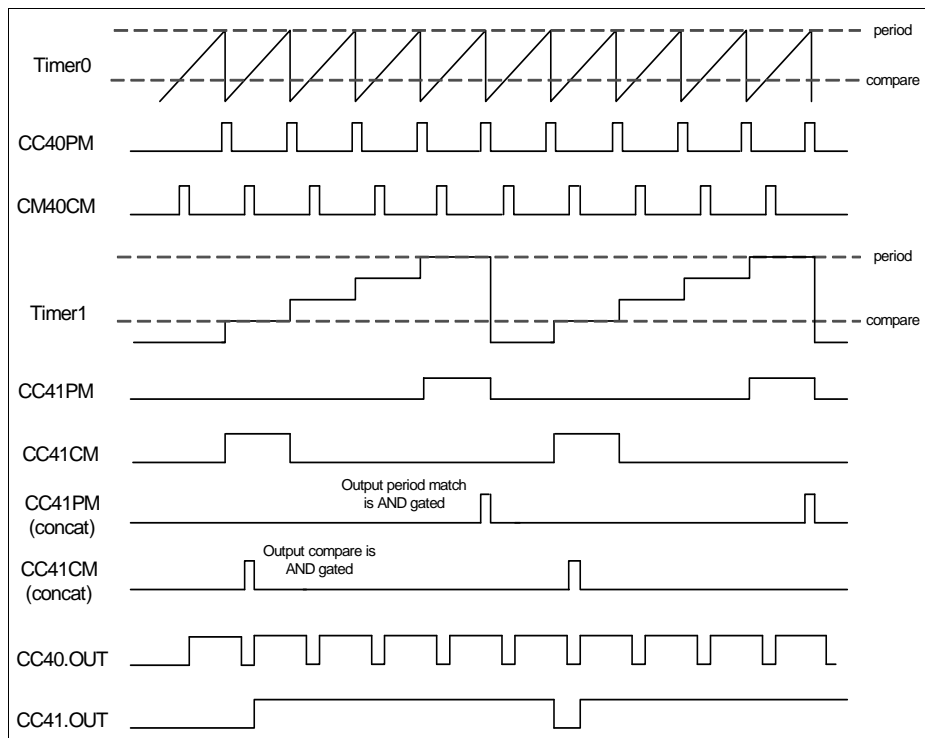

Figure 17-47 32 bit concatenation timing diagram

Note: The counting direction of the concatenated timer needs to be fixed. The timer can count up or count down, but the direction cannot be updated on the fly.

Figure 17-48 gives an overview of the timer concatenation logic. Notice that all the mechanism is controlled solely by the **CC4yCMC.TCE** bitfield.

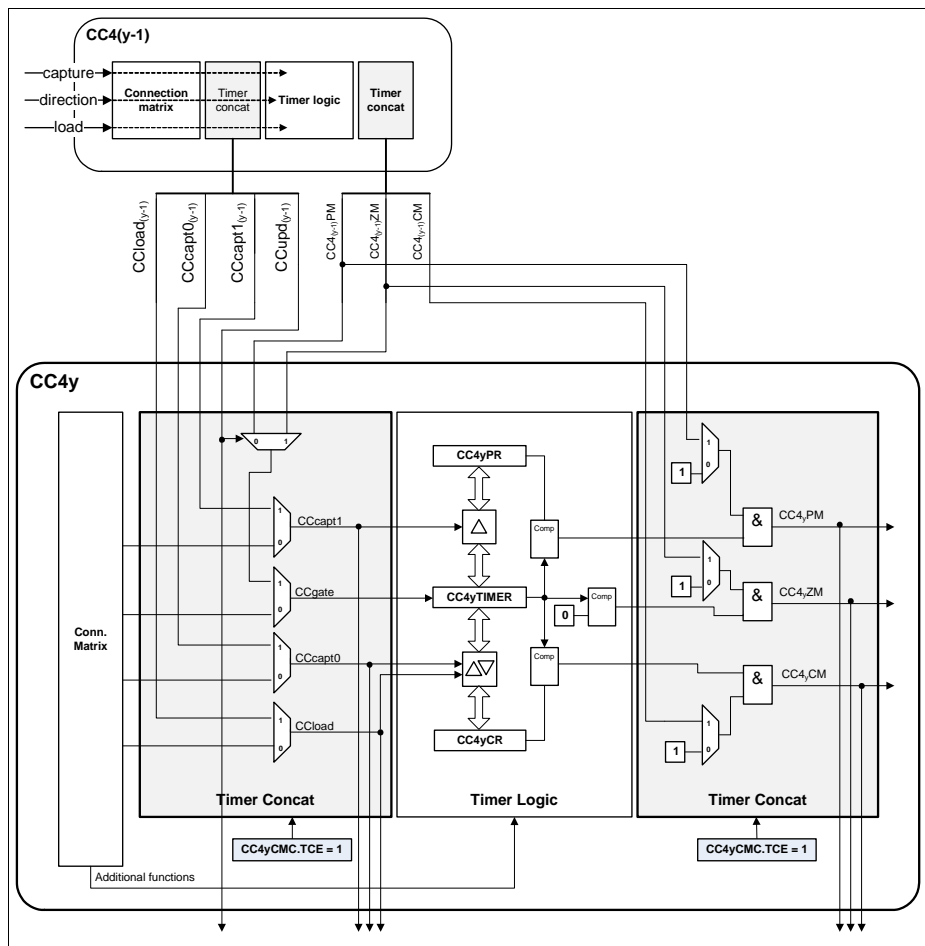

Figure 17-48 Timer concatenation control logic

17.2.10 PWM Dithering

The CCU4 has an automatic PWM dithering insertion function. This functionality can be used with very slow control loops that cannot update the period/compare values in a fast manner, and by that fact the loop can lose precision on long runs. By introducing dither on the PWM signal, the average frequency/duty cycle is then compensated against that error.

Each slice contains a dither control unit, see [Figure 17-49](#).

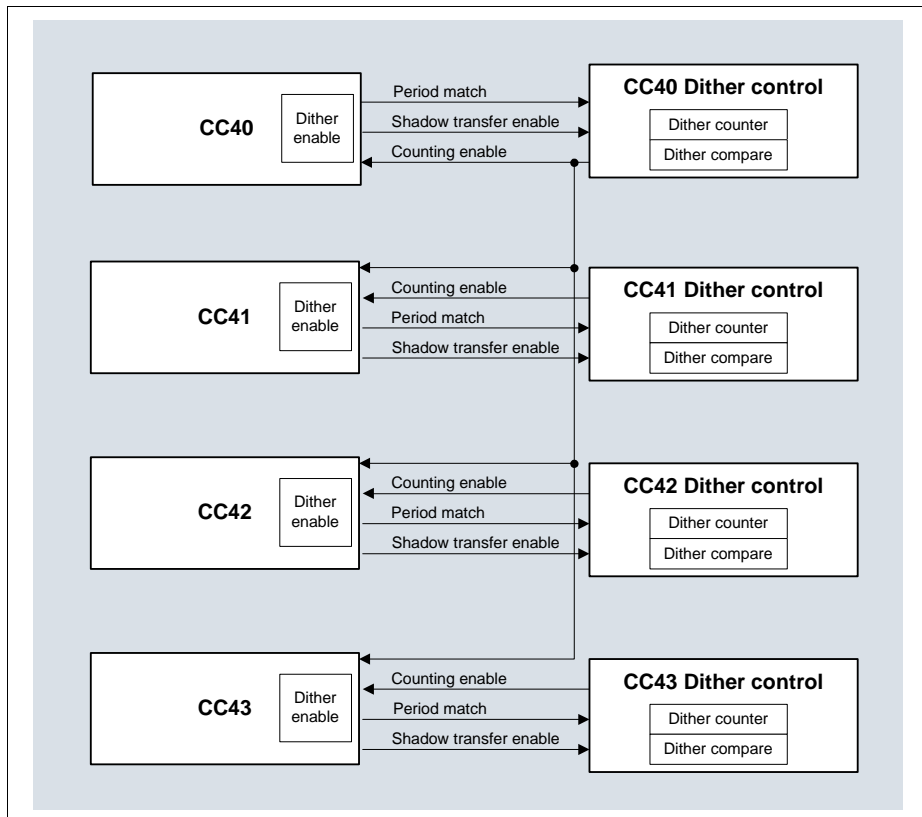

Figure 17-49 Dither structure overview

The dither control unit contains a 4 bit counter and a compare value. The four bit counter is incremented every time that a period match occurs. The counter works in a bit reverse mode so the distribution of increments stays uniform over 16 counter periods, see [Table 17-5](#).

Table 17-5 Dither bit reverse counter

| counter[3] | counter[2] | counter[1] | counter[0] |
|------------|------------|------------|------------|
| 0 | 0 | 0 | 0 |
| 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 |
| 1 | 1 | 0 | 0 |
| 0 | 0 | 1 | 0 |
| 1 | 0 | 1 | 0 |
| 0 | 1 | 1 | 0 |
| 1 | 1 | 1 | 0 |
| 0 | 0 | 0 | 1 |
| 1 | 0 | 0 | 1 |
| 0 | 1 | 0 | 1 |
| 1 | 1 | 0 | 1 |
| 0 | 0 | 1 | 1 |
| 1 | 0 | 1 | 1 |
| 0 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 |

The counter is then compared against a programmed value, **CC4yDIT.DCV**. If the counter value is smaller than the programmed value, a gating signal is generated that can be used to extend the period, to delay the compare or both (controlled by the **CC4yTC.DITHE** field, see [Table 17-6](#)) for one clock cycle.

Table 17-6 Dither modes

| DITHE[1] | DITH[0] | Mode |
|----------|---------|--|
| 0 | 0 | Dither is disabled |
| 0 | 1 | Period is increased by 1 cycle |
| 1 | 0 | Compare match is delayed by 1 cycle |
| 1 | 1 | Period is increased by 1 cycle and compare is delayed by 1 cycle |

The dither compare value also has an associated shadow register that enables concurrent update with the period/compare register of CC4y. The control logic for the dithering unit is represented on [Figure 17-50](#).

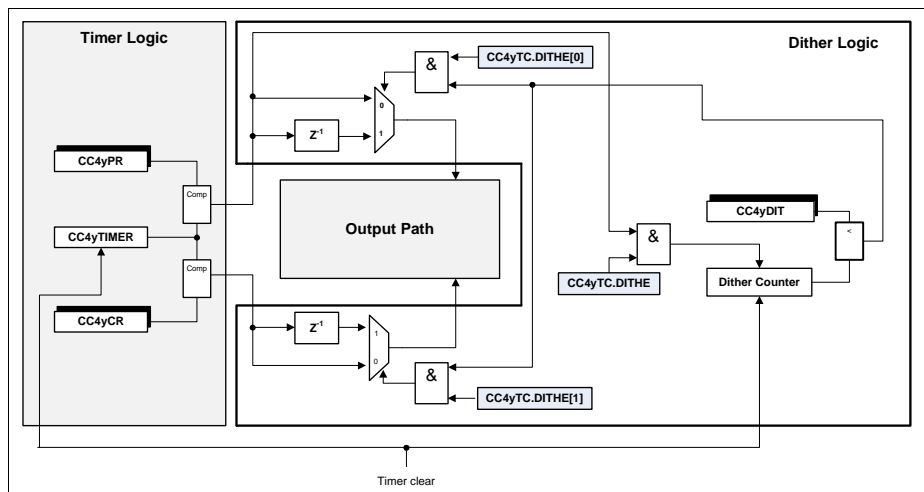

Figure 17-50 Dither control logic

Figure 17-51 to Figure 17-56 show the effect of the different configurations for the dithering function, **CC4yTC.DITHE**, for both counting schemes, Edge and Center Aligned mode. In each figure, the bit reverse scheme is represented for the dither counter and the compare value was programmed with the value 8_H . In each figure, the variable T , represents the period of the counter, while the variable d indicates the duty cycle (status bit is set HIGH).

Figure 17-51 Dither timing diagram in edge aligned - **CC4yTC.DITHE** = 01_B

Figure 17-52 Dither timing diagram in edge aligned - $\text{CC4yTC.DITHE} = 10_{\text{b}}$

Figure 17-53 Dither timing diagram in edge aligned - $\text{CC4yTC.DITHE} = 11_{\text{b}}$

Figure 17-54 Dither timing diagram in center aligned - $\text{CC4yTC.DITHE} = 01_{\text{b}}$

Figure 17-55 Dither timing diagram in center aligned - $CC4yTC.DITHE = 10_B$

Figure 17-56 Dither timing diagram in center aligned - $CC4yTC.DITHE = 11_B$

Note: When using the dither, is not possible to select a period value of FS when in edge aligned mode. In center aligned mode, the period value must be at least $FS - 2$.

17.2.11 Prescaler

The CCU4 contains a 4 bit prescaler that can be used in two operating modes for each individual slice:

- normal prescaler mode
- floating prescaler mode

The run bit of the prescaler can be set/cleared by SW by writing into the registers, **GIDLC.SPRB** and **GIDLS.CPRB** respectively, and it can also be cleared by the run bit of a specific slice. With the last mechanism, the run bit of the prescaler is cleared one clock cycle after the clear of the run bit of the selected slice. To select which slice can perform this action, one should program the **GCTRL.PRBC** register.

17.2.11.1 Normal Prescaler Mode

In Normal prescaler mode the clock fed to the CC4y counter is a normal fixed division by N, accordingly to the value set in the **CC4yPSC**.PSIV register. The values for the possible division values are listed in **Table 17-7**. The **CC4yPSC**.PSIV value is only modified by a SW access. Notice that each slice has a dedicated prescaler value selector (**CC4yPSC**.PSIV), which means that the user can select different counter clocks for each Timer Slice (CC4y).

Table 17-7 Timer clock division options

| CC4yPSC.PSIV | Resulting clock |
|---------------------|------------------------|
| 0000 _B | f_{CCU4} |
| 0001 _B | $f_{CCU4}/2$ |
| 0010 _B | $f_{CCU4}/4$ |
| 0011 _B | $f_{CCU4}/8$ |
| 0100 _B | $f_{CCU4}/16$ |
| 0101 _B | $f_{CCU4}/32$ |
| 0110 _B | $f_{CCU4}/64$ |
| 0111 _B | $f_{CCU4}/128$ |
| 1000 _B | $f_{CCU4}/256$ |
| 1001 _B | $f_{CCU4}/512$ |
| 1010 _B | $f_{CCU4}/1024$ |
| 1011 _B | $f_{CCU4}/2048$ |
| 1100 _B | $f_{CCU4}/4096$ |
| 1101 _B | $f_{CCU4}/8192$ |
| 1110 _B | $f_{CCU4}/16384$ |
| 1111 _B | $f_{CCU4}/32768$ |

17.2.11.2 Floating Prescaler Mode

The floating prescaler mode can be used individually in each slice by setting the register **CC4yTC**.FPE = 1_B. With this mode, the user can not only achieve a better precision on the counter clock for compare operations but also reduce the SW read access for the capture mode.

The floating prescaler mode contains additionally to the initial configuration value register, **CC4yPSC**.PSIV, a compare register, **CC4yFPC**.PCMP with an associated shadow register mechanism.

Capture/Compare Unit 4 (CCU4)

Figure 17-57 shows the structure of the prescaler in floating mode when the specific slice is in compare mode (no external signal is used for capture). In this mode, the value of the clock division is incremented by 1_D every time that a timer overflow/underflow (overflow if in Edge Aligned Mode, underflow if in Center Aligned Mode) occurs.

In this mode, the Compare Match from the timer is AND gated with the Compare Match of the prescaler and every time that this event occurs, the value of the clock division is updated with the **CC4yPSC.PSIV** value in the immediately next timer overflow/underflow event.

The shadow transfer of the floating prescaler compare value, **CC4yFPC.PCMP**, is done following the same rules described on **Section 17.2.5.2**.

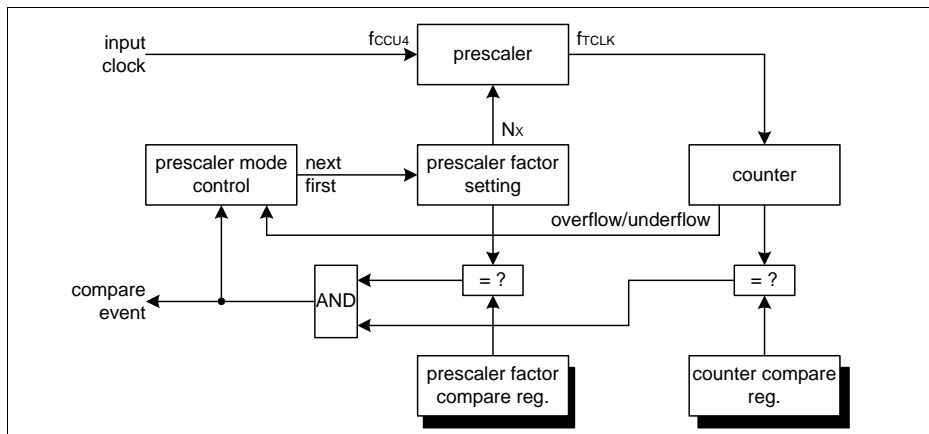

Figure 17-57 Floating prescaler in compare mode overview

When the specific CC4y is operating in capture mode (when at least one external signal is decoded as capture functionality), the actual value of the clock division also needs to be stored every time that a capture event occurs. The floating prescaler can have up to 4 capture registers (the maximum number of capture registers is dictated by the number of capture registers used in the specific slice).

The clock division value continues to be incremented by 1_D every time that a timer overflow (in capture mode, the slice is always operating in Edge Aligned Mode) occurs and it is loaded with the PSIV value every time that a capture triggers is detected.

See the **Section 17.2.12.2** for a full description of the usage of the floating prescaler mode in conjunction with compare and capture modes.

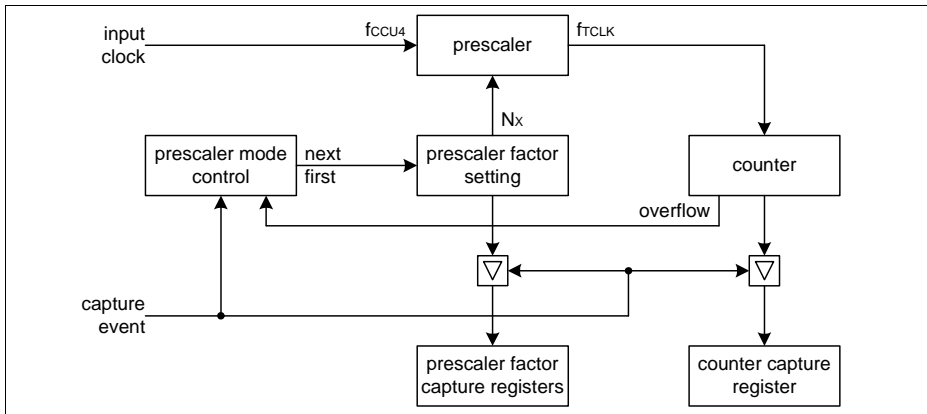

Figure 17-58 Floating Prescaler in capture mode overview

17.2.12 CCU4 Usage

17.2.12.1 PWM Signal Generation

The CCU4 offers a very flexible range in duty cycle configurations. This range is comprised between 0 to 100%.

To generate a PWM signal with a 100% duty cycle in Edge Aligned Mode, one should program the compare value, **CC4yCR.CR**, to 0000_H, see [Figure 17-59](#).

In the same manner a 100% duty cycle signal can be generated in Center Aligned Mode, see [Figure 17-60](#).

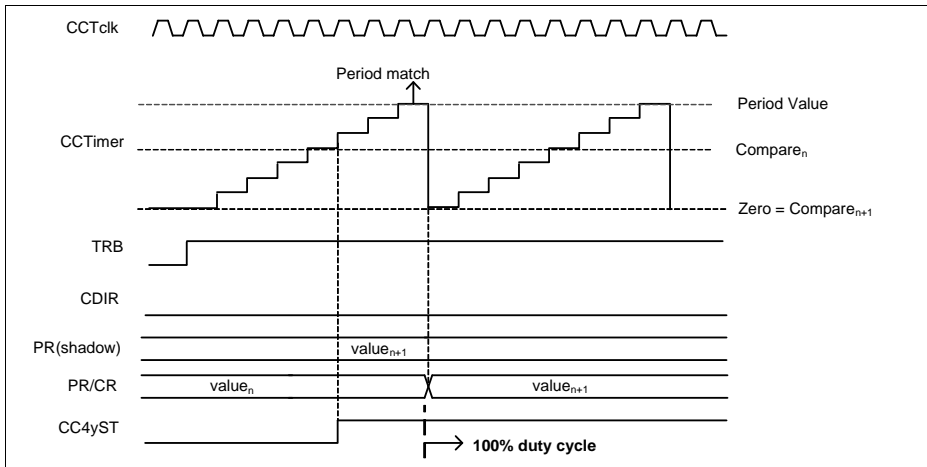

Figure 17-59 PWM with 100% duty cycle - Edge Aligned Mode

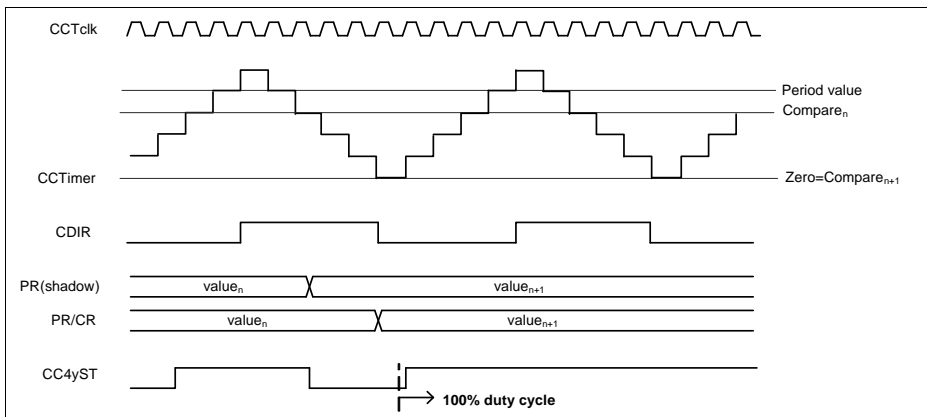

Figure 17-60 PWM with 100% duty cycle - Center Aligned Mode

To generate a PWM signal with 0% duty cycle in Edge Aligned Mode, the compare register should be set with the value programmed into the period value plus 1. In the case that the timer is being used with the full 16 bit capability (counting from 0 to 65535), setting a value bigger than the period value into the compare register is not possible and therefore the smallest duty cycle that can be achieved is 1/FS, see [Figure 17-61](#).

In Center Aligned Mode, the counter is never running from 0 to 65535_D, due to the fact that it has to overshoot for one clock cycle the value set in the period register. Therefore the user never has a FS counter, which means that generating a 0% duty cycle signal is

Capture/Compare Unit 4 (CCU4)

always possible by setting a value in the compare register bigger than the one programmed into the period register, see [Figure 17-62](#).

Figure 17-61 PWM with 0% duty cycle - Edge Aligned Mode

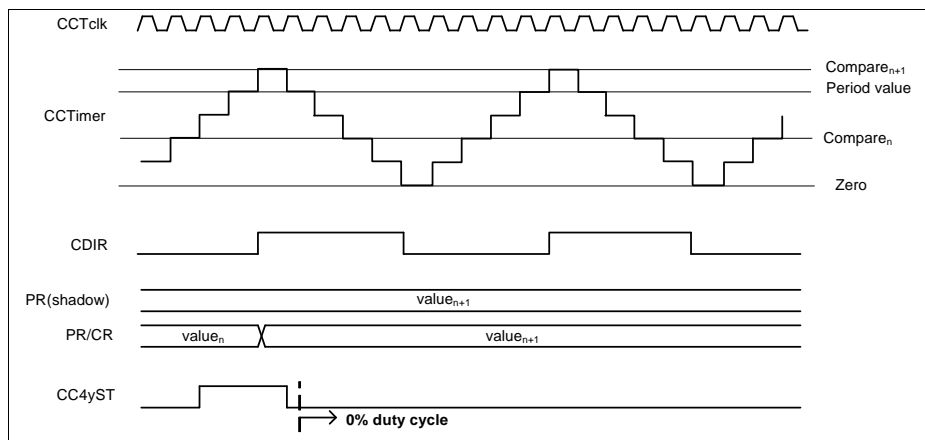

Figure 17-62 PWM with 0% duty cycle - Center Aligned Mode

17.2.12.2 Prescaler Usage

In Normal Prescaler Mode, the frequency of the f_{clk} fed to the specific CC4y is chosen from the [Table 17-7](#), by setting the **CC4yPSC.PSIV** with the required value.

In Floating Prescaler Mode, the frequency of the f_{clk} can be modified over a selected timeframe, within the values specified in [Table 17-7](#). This mechanism is specially useful if, when in capture mode, the dynamic of the capture triggers is very slow or unknown.

Capture/Compare Unit 4 (CCU4)

In Capture Mode, the Floating Prescaler value is incremented by 1 every time that a timer overflow happens and it is set with the initial programmed value when a capture event happens, see [Figure 17-63](#).

When using the Floating Prescaler Mode in Capture Mode, the timer should be cleared each time that a capture event happens, **CC4yTC.CAPC** = 11_B. By operating the Capture mode in conjunction with the Floating Prescaler, even for capture signals that have a periodicity bigger than 16 bits, it is possible to use just a single CCU4 Timer Slice without monitoring the interrupt event of the timer overflow, cycle by cycle. For this the user just needs to know what is the timer captured value and the actual prescaler configuration at the time that the capture event occurred. These values are contained in each CC4yCxV register.

Figure 17-63 Floating Prescaler capture mode usage

When in Compare Mode, the Floating Prescaler function may be used to achieve a fractional PWM frequency or to perform some frequency modulation.

The same incrementing by 1_D mechanism is done every time that an overflow/underflow of the Timer occurs and the actual Prescaler value, doesn't match the one programmed into the **CC4yFPC.PCMP** register.

When a Compare Match from the Timer occurs and the actual Prescaler value is equal to the one programmed on the **CC4yFPC.PCMP** register, then the Prescaler value is set with the initial value, **CC4yPSC.PSIV**, when the next occurrence of a timer overflow/underflow.

In [Figure 17-64](#), the Compare value of the Floating Prescaler was set to PSIV + 2. Every time that a timer overflow occurs, the value of the Prescaler is incremented by 1, which means that if we give f_{tclk} as the reference frequency for the **CC4yPSC.PSIV** value, we have $f_{tclk}/2$ for **CC4yPSC.PSIV + 1** and $f_{tclk}/4$ for **CC4yPSC.PSIV + 2**.

The period over time of the counter becomes:

$$Period = (1/f_{tclk} + 2/f_{tclk} + 4/f_{tclk}) / 3 \quad (17.10)$$

Capture/Compare Unit 4 (CCU4)

The same mechanism is used in Center Aligned Mode, but to keep the rising arcade and falling arcade always symmetrical, instead of the overflow of the timer, the underflow is used, see [Figure 17-65](#).

Figure 17-64 Floating Prescaler compare mode usage - Edge Aligned

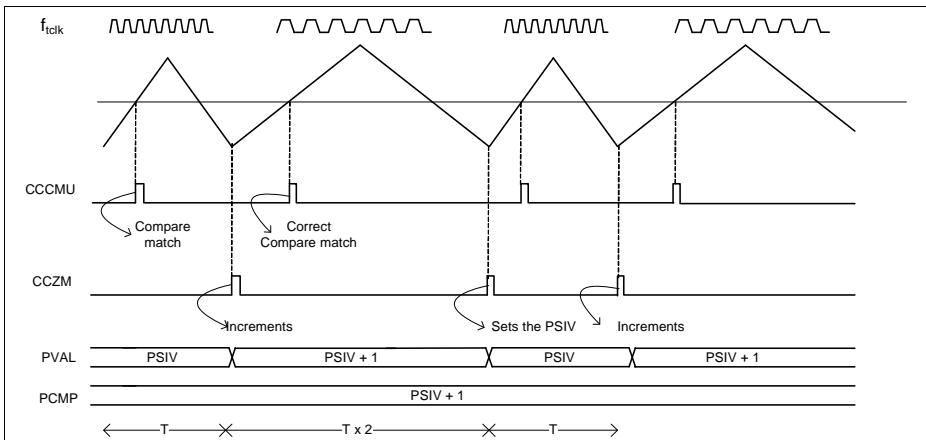

Figure 17-65 Floating Prescaler compare mode usage - Center Aligned

17.2.12.3 PWM Dither

The Dither functionality can be used to achieve a very fine precision on the periodicity of the output state in compare mode. The value set in the dither compare register, [CC4yDIT.DCV](#) is crosschecked against the actual value of the dither counter and every

Capture/Compare Unit 4 (CCU4)

time that the dither counter is smaller than the comparison value one of the follows actions is taken:

- The period is extended for 1 clock cycle - **CC4yTC.DITHE** = 01_B; in edge aligned mode
- The period is extended for 2 clock cycles - **CC4yTC.DITHE** = 01_B; in center aligned mode
- The comparison match while counting up (**CC4yTCST.CDIR** = 0_B) is delayed (this means that the status bit is going to stay in the SET state 1 cycle less) for 1 clock cycle - **CC4yTC.DITHE** = 10_B;
- The period is extended for 1 clock cycle and the comparison match while counting up is delayed for 1 clock cycle - **CC4yTC.DITHE** = 11_B; in edge aligned mode
- The period is extended for 2 clock cycles and the comparison match while counting up is delayed for 1 clock cycle; center aligned mode

The bit reverse counter distributes the number programmed in the **CC4yDIT.DCV** throughout a window of 16 timer periods.

Table 17-8 describes the bit reverse distribution versus the programmed value on the **CC4yDIT.DCV** field. The fields marked as '0' indicate that in that counter period, one of the above described actions, is going to be performed.

Table 17-8 Bit reverse distribution

| | DCV | | | | | | | | | | | | | | | |
|----------------|-----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|
| Dither counter | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 8 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| C | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 |
| 2 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| A | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| 6 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| E | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 |

Table 17-8 Bit reverse distribution (cont'd)

| | DCV | | | | | | | | | | | | | | | |
|-----------------------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Dither counter | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| 7 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| F | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

The bit reverse distribution versus the programmed **CC4yDIT**.DCV value results in the following values for the Period and duty cycle:

$$\text{DITHE} = 01_{\text{B}}$$

$$\text{Period} = [(16 - \text{DCV}) \times T + \text{DCV} \times (T + 1)]/16; \text{ in Edge Aligned Mode} \quad (17.11)$$

$$\text{Duty cycle} = [(16 - \text{DCV}) \times d/T + \text{DCV} \times (d+1)/(T + 1)]/16; \text{ in Edge Aligned Mode} \quad (17.12)$$

$$\text{Period} = [(16 - \text{DCV}) \times T + \text{DCV} \times (T + 2)]/16; \text{ in Center Aligned Mode} \quad (17.13)$$

$$\text{Duty cycle} = [(16 - \text{DCV}) \times d/T + \text{DCV} \times (d+2)/(T + 2)]/16; \text{ in Center Aligned Mode} \quad (17.14)$$

$$\text{DITHE} = 10_{\text{B}}$$

$$\text{Period} = T ; \text{ in Edge Aligned Mode} \quad (17.15)$$

$$\text{Duty cycle} = [(16 - \text{DCV}) \times d/T + \text{DCV} \times (d-1)/T]/16; \text{ in Edge Aligned Mode} \quad (17.16)$$

$$\text{Period} = T ; \text{ in Center Aligned Mode} \quad (17.17)$$

$$\text{Duty cycle} = [(16 - \text{DCV}) \times d/T + \text{DCV} \times (d-1)/T]/16; \text{ in Center Aligned Mode} \quad (17.18)$$

$$\text{DITHE} = 11_{\text{B}}$$

$$\text{Period} = [(16 - \text{DCV}) \times T + \text{DCV} \times (T + 1)]/16; \text{ in Edge Aligned Mode} \quad (17.19)$$

$$\text{Duty cycle} = [(16 - \text{DCV}) \times d/T + \text{DCV} \times d/(T + 1)]/16; \text{ in Edge Aligned Mode} \quad (17.20)$$

$$\text{Period} = [(16 - \text{DCV}) \times T + \text{DCV} \times (T + 2)]/16; \text{ in Center Aligned Mode} \quad (17.21)$$

$$\text{Duty cycle} = [(16 - \text{DCV}) \times d/T + \text{DCV} \times (d+1)/(T + 2)]/16; \text{ in Center Aligned Mode} \quad (17.22)$$

where:

T - Original period of the signal, see [Section 17.2.5.1](#)

d - Original duty cycle of the signal, see [Section 17.2.5.1](#)

17.2.12.4 Capture Mode Usage

Each Timer Slice can make use of 2 or 4 capture registers. Using only 2 capture registers means that only 1 Event was linked to a captured trigger. To use the four capture registers, both capture triggers need to be mapped into an Event (it can be the same signal with different edges selected or two different signals) or the **CC4yTC.SCE** field needs to be set to 1, which enables the linking of the 4 capture registers.

The internal slice mechanism for capturing is the same for the capture trigger 1 or capture trigger 0.

Different Capture Events - SCE = 0_B

Capture trigger 1 (CCcapt1) is appointed to the capture register 2, **CC4yC2V** and capture register 3, **CC4yC3V**, while trigger 0 (CCcapt0) is appointed to capture register 1, **CC4yC1V** and 0, **CC4yC0V**.

In each CCcapt0 event, the timer value is stored into **CC4yC1V** and the value of the **CC4yC1V** is transferred into the **CC4yC0V**.

In each CCcapt1 event, the timer value is stored into capture register **CC4yC3V** and the value of the capture register **CC4yC3V** is transferred into **CC4yC2V**.

The capture/transfer mechanism only happens if the specific register is not full. A capture register becomes full when receives a new value and becomes empty after the SW has read back the value.

The full flag is cleared every time that the SW reads back the **CC4yC0V**, **CC4yC1V**, **CC4yC2V** or **CC4yC3V** register. The SW can be informed of a new capture trigger by enabling the interrupt source linked to the specific Event. This means that every time that a capture is made an interrupt pulse is generated.

In the case that the Floating Prescaler Mode is being used, the actual value of the clock division is also stored in the capture register (CC4yCxV).

Figure 17-66 shows an example of how the capture/transfer may be used in a Timer Slice that is using an external signal as count function (to measure the velocity of a rotating device), and an equidistant capture trigger that is used to dictate the timestamp for the velocity calculation (two Timer waveforms are plotted, one that exemplifies the clearing of the timer in each capture event and another without the clearing function active).

Figure 17-66 Capture mode usage - single channel

Same Capture Event - SCE = 1_B

If the **CC4yTC.SCE** is set to 1_B, all the four capture registers are chained together, emulating a fifo with a depth of 4. In this case, only the capture trigger 1, CCcapt1, is used to perform a capture event.

As an example for this mode, one can consider the case where one Timer Slice is being used in capture mode with SCE = 1_B, with another external signal that controls the counting. This timer slice can be incremented at different speeds, depending on the frequency of the counting signal.

An additional Timer Slice is used to control the capture trigger, dictating the time stamp for the capturing.

A simple scheme for this can be seen in **Figure 17-67**. The CC40ST output of slice 0 was used as capture trigger in the CC41 slice (active on rising and falling edge). The CC40ST output is used as known timebase marker, while the slice timer used for capture is being controlled by external events, e.g. external count.

Due to the fact that we have available 4 capture registers, every time that the SW reads back the complete set of values, 3 speed profiles can be measured.

Figure 17-67 Three Capture profiles - CC4yTC.SCE = 1_b

To calculate the three different profiles in [Figure 17-67](#), the 4 capture registers need to be read during the pointed read window. After that, the profile calculation is done:

$$\text{Profile 1} = \text{CC41C1V}_{\text{info}} - \text{CC41C0V}_{\text{info}}$$

$$\text{Profile 2} = \text{CC41C2V}_{\text{info}} - \text{CC41C1V}_{\text{info}}$$

Profile 3= CC41C3V_{info} - CC41C2V_{info}

Note: This is an example and therefore several Timer Slice configurations and software loops can be implemented.

High Dynamics Capturing

In some cases the dynamics of the capture trigger(s) may vary greatly over time. This will impose that the software needs to be prepared for the worst case scenario, where the frequency of the capture triggers may be very high. In applications where cycle-by-cycle calculation is needed (calculation in each capture trigger), then this constraints needs to be met by the software. Nevertheless for applications where a cycle-by-cycle calculation is not needed, the software can read back the FIFO data register in a periodic base and fetch all the data that has been captured so far, **Figure 17-68**.

Figure 17-68 High dynamics capturing with software controlled timestamp

In this scenario, the software/CPU will read back the complete set of capture registers (2 or 4 depending on the chosen configuration), every time that an interrupt is triggered from the timestamp timer (the periodicity of this timer can also be adjusted on-the-fly).

Due to the fact that every capture register offers a full flag status bit, the software/CPU can always read back the complete set of registers. At the time of the data processing, this full flag is then checked, indicating if this value needs to be processed or not.

This FIFO read back functionality can also be used for applications that impose a heavy load on the system, which may not guarantee fixed access times to read back the captured data.

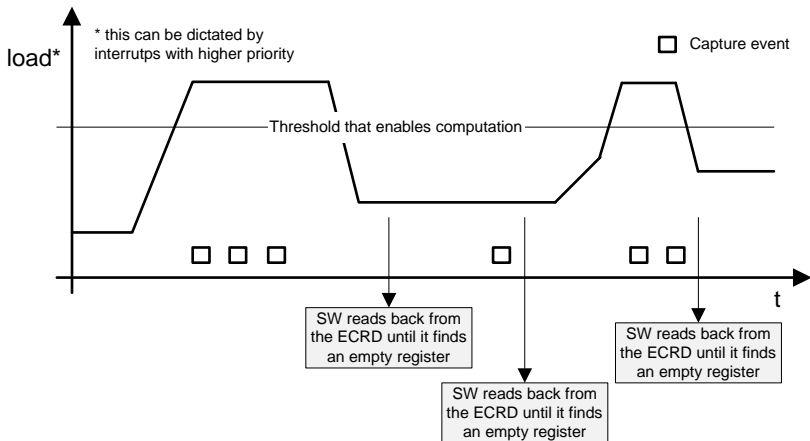

Figure 17-69 Extended read back during high load

Capture Grouping

In applications where multiple capture Timers are needed and the priority of the capture routines, does not imply that a cycle-by-cycle calculation needs to be done for every event, it may be suitable to group all the timers in the same CCU4x unit, [Figure 17-70](#).

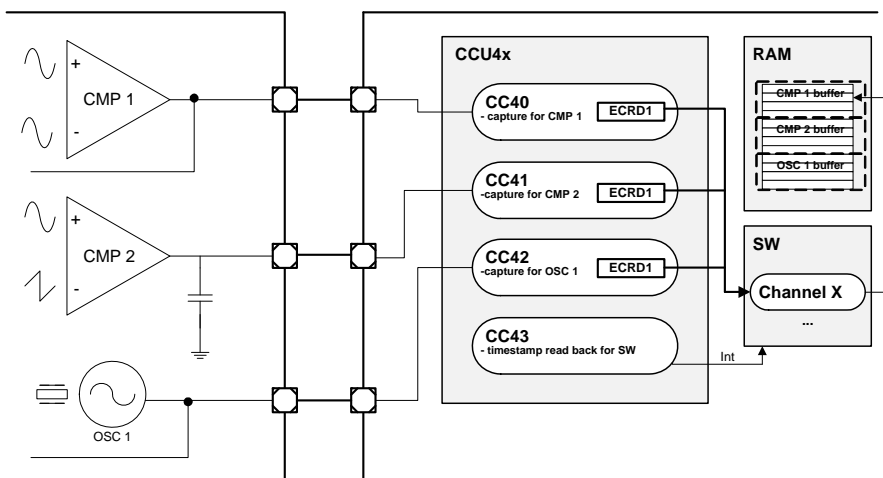

Figure 17-70 Capture grouping with extended read back

Capture/Compare Unit 4 (CCU4)

By setting the ECM bitfield for the Timer Slices used for capturing, the extended read back mode enables the reading back of data always in the proper capture order (from oldest to newest data). A timestamp timer is then used to trigger the Software/CPU to read back all the capture data present in the Timer Slices.

Every time that the interrupt is sensed, the Software/CPU (in this example) reads back the complete set of capture registers (via the ECRD address) for all Timer Slices. Due to the fact that each data read has a full flag indicator, the Software/CPU can read back the complete set of capture registers from all timers. This allows a fixed memory allocation that is as big as the number of captured registers, **Figure 17-71** (in this example 4 capture registers for each Timer Slice are being used).

The additional lost value bitfield (LCV) on the header of each ECRD data, will indicate if any capture trigger was lost between read operations (this can happen if the capture triggers are faster than the routine that is reading back the values).

Figure 17-71 Memory structure for extended read back

17.3 Service Request Generation

Each CCU4 slice has an interrupt structure as the one in [Figure 17-72](#). The register **CC4yINTS** is the status register for the interrupt sources. Each dedicated interrupt

Capture/Compare Unit 4 (CCU4)

source can be set or cleared by SW, by writing into the specific bit in the **CC4ySWS** and **CC4ySWR** registers respectively.

Each interrupt source can be enabled/disabled via the **CC4yINTE** register. An enabled interrupt source will always generate a pulse on the service request line even if the specific status bit was not cleared. **Table 17-9** describes the interrupt sources of each CCU4 slice.

The interrupt sources, Period Match while counting up and one Match while counting down are ORed together. The same mechanism is applied to the Compare Match while counting up and Compare Match while counting down.

The interrupt sources for the external events are directly linked with the configuration set on the **CC4yINS.EVxEM**. If an event is programmed to be active on both edges, that means that service request pulse is going to be generated when any transition on the external signal is detected. If the event is linked with a level function, the **CC4yINS.EVxEM** still can be programmed to enable a service request pulse. The TRAP event doesn't need any of extra configuration for generating the service request pulse when the slice enters the TRAP state.

Table 17-9 Interrupt sources

| Signal | Description |
|----------------|--|
| CCINEV0_E | Event 0 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCINEV1_E | Event 1 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCINEV2_E | Event 2 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCPM_U | Period Match while counting up |
| CCCM_U | Compare Match while counting up |
| CCCM_D | Compare Match while counting down |
| CCOM_D | One Match while counting down |
| Trap state set | Entering Trap State. Will set the E2AS |

Capture/Compare Unit 4 (CCU4)

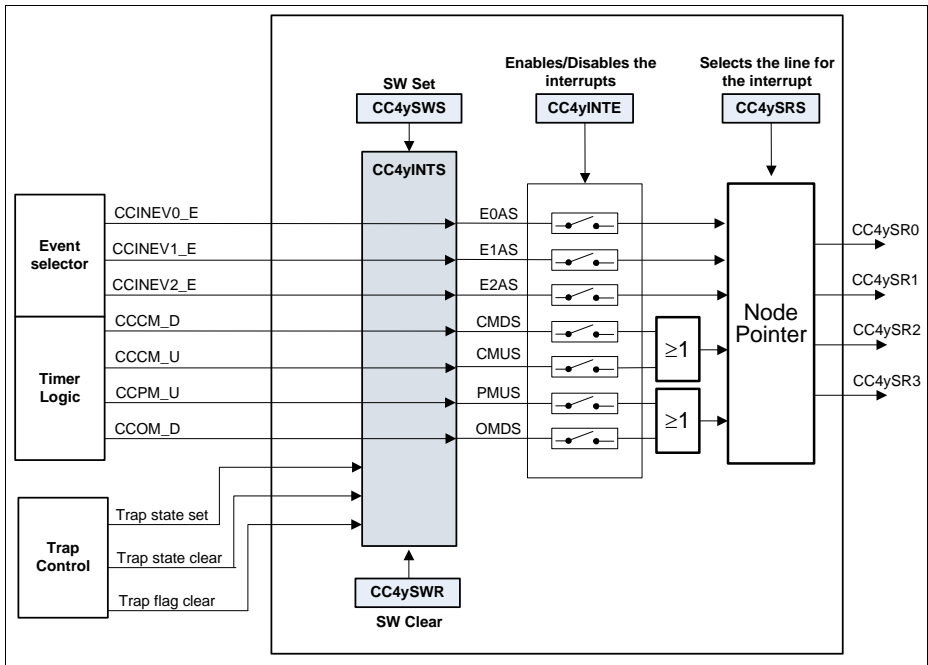

Figure 17-72 Slice interrupt structure overview

Each of the interrupt events can then be forwarded to one of the slice's four service request lines, [Figure 17-73](#). The value set on the **CC4ySRS** controls which interrupt event is mapped into which service request line.

Figure 17-73 Slice Interrupt Node Pointer overview

The four service request lines of each slice are OR together inside the kernel of the CCU4, see [Figure 17-74](#). This means that there are only four service request lines per CCU4, that can have in each line interrupt requests coming from different slices.

Figure 17-74 CCU4 service request overview

17.4 Debug Behavior

In suspend mode, the functional clocks for all slices as well the prescaler are stopped. The registers can still be accessed by the CPU (read only). This mode is useful for debugging purposes, e.g. where the current device status should be frozen in order to get a snapshot of the internal values. In suspend mode, all the slice timers are stopped. The suspend mode is non-intrusive concerning the register bits. This means register bits are not modified by hardware when entering or leaving the suspend mode.

Entry into suspend mode can be configured at the kernel level by means of the field **GCTRL.SUSCFG**.

The module is only functional after the suspend signal becomes inactive.

17.5 Power, Reset and Clock

The following sections describe the operating conditions, characteristics and timing requirements for the CCU4. All the timing information is related to the module clock, f_{CCU4} .

17.5.1 Clocks

Module Clock

The module clock of the CCU4 module is described in the SCU chapter as f_{PCLK} .

The bus interface clock of the CCU4 module is described in the SCU chapter as f_{MCLK} .

Capture/Compare Unit 4 (CCU4)

It is possible to disable the module clock for the CCU4 via the **GSTAT** register, nevertheless, there may be a dependency of the f_{ccu4} through the different CCU4 instances. One should address the SCU Chapter for a complete description of the product clock scheme.

If module clock dependencies exist through different IP instances, then one can disable the module clock internally inside the specific CCU4, by disabling the prescaler (**GSTAT.PRB** = 0_B).

External Clock

It is possible to use an external clock as source for the prescaler, and consequently for all the timer Slices, CC4y. This external source can be connected to one of the CCU4x.CLK[C...A] inputs.

This external source is nevertheless synchronized against f_{ccu4} .

Table 17-10 External clock operating conditions

| Parameter | Symbol | Values | | | Unit | Note / Test Condition |
|-----------|---------------|--------------------|------|--------------|------|------------------------------|
| | | Min. | Typ. | Max. | | |
| Frequency | f_{eclk} | — | — | $f_{ccu4}/4$ | MHz | |
| ON time | ton_{eclk} | $2T_{ccu4}^{1)2)}$ | — | — | ns | |
| OFF time | $toff_{eclk}$ | $2T_{ccu4}^{1)2)}$ | — | — | ns | Only the rising edge is used |

1) Only valid if the signal was not previously synchronized/generated with the f_{ccu4} clock (or a synchronous clock)

2) 50% duty cycle is not obligatory

17.5.2 Power

The CCU4 is inside the power core domain, therefore no special considerations about power up or power down sequences need to be taken. For an explanation about the different power domains, please address the SCU (System Control Unit) chapter.

An internal power down mode for the CCU4, can be achieved by disabling the clock inside the CCU4 itself. For this one should set the **GSTAT** register with the default reset value (via the idle mode set register, **GIDLS**).

17.6 Initialization and System Dependencies

17.6.1 Initialization Sequence

The initialization sequence for an application that is using the CCU4, should be the following:

1st Step: Enable the CCU4 clock via the specific SCU register, CGATCLR0.

2nd Step: Enable the prescaler block, by writing 1_B to the **GIDLC**.SPRB field.

3rd Step: Configure the global CCU4 register **GCTRL**

4th Step: Configure all the registers related to the required Timer Slice(s) functions, including the interrupt/service request configuration.

5th Step: If needed, configure the startup value for a specific Compare Channel Status, of a Timer Slice, by writing 1_B to the specific **GCSS**.SyTS.

6th Step: Enable the specific timer slice(s), CC4y, by writing 1_B to the specific **GIDLC**.CSyl.

7th Step: For all the Timer Slices that should be started synchronously via SW, the specific system register localized in the SCU, CCUCON, that enables a synchronous timer start should be addressed. The SCU.GSC4x input signal needs to be configured previously as a start function, see [Section 17.2.7.1](#).

17.6.2 System Dependencies

Each CCU4 may have different dependencies regarding module and bus clock frequencies. This dependencies should be addressed in the SCU and System Architecture Chapters.

Dependencies between several peripherals, regarding different clock operating frequencies may also exist. This should be addressed before configuring the connectivity between the CCU4 and some other peripheral.

The following topics must be taken into consideration for good CCU4 and system operation:

- CCU4 module clock must be at maximum two times faster than the module bus interface clock
- Module input triggers for the CCU4 must not exceed the module clock frequency (if the triggers are generated internally in the device)
- Module input triggers for the CCU4 must not exceed the frequency dictated in [Section 17.5.1](#)
- Frequency of the CCU4 outputs used as triggers/functions on other modules, must be crosschecked on the end point
- Applying and removing CCU4 from reset, can cause unwanted operations in other modules. This can occur if the modules are using CCU4 outputs as triggers/functions.

17.7 Registers

Registers Overview

The absolute register address is calculated by adding:
Module Base Address + Offset Address

Table 17-11 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|-----------------------|-----------------------|------|
| CCU40 | 48040000 _H | 4804FFFF _H | |

1) The absolute register address is calculated as follows:

Module Base Address + Offset Address (shown in this column)

17.7.1 Global Registers

GCTRL

The register contains the global configuration fields that affect all the timer slices inside CCU4.

GCTRL

Global Control Register

(0000_H)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|------|----|-------|-------|-------|-------|--------|----|----|----|------|----|----|----|------|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| MSDE | | MSE 3 | MSE 2 | MSE 1 | MSE 0 | SUSCFG | | 0 | | PCIS | | 0 | | PRBC | |
| rw | | rw | rw | rw | rw | rw | | r | | rw | | r | | rw | |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------|-------|------|--|
| PRBC | [2:0] | rw | Prescaler Clear Configuration This register controls how the prescaler Run Bit and internal registers are cleared. 000 _B SW only 001 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC40 is cleared. 010 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC41 is cleared. 011 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC42 is cleared. 100 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC43 is cleared. |
| PCIS | [5:4] | rw | Prescaler Input Clock Selection 00 _B Module clock 01 _B CCU4x.ECLKA 10 _B CCU4x.ECLKB 11 _B CCU4x.ECLKC |
| SUSCFG | [9:8] | rw | Suspend Mode Configuration This field controls the entering in suspend mode for all the CAPCOM4 slices. 00 _B Suspend request ignored. The module never enters in suspend 01 _B Stops all the running slices immediately. Safe stop is not applied. 10 _B Stops the block immediately and clamps all the outputs to PASSIVE state. Safe stop is applied. 11 _B Waits for the roll over of each slice to stop and clamp the slices outputs. Safe stop is applied. |
| MSE0 | 10 | rw | Slice 0 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 0 can be requested not only by SW but also via the CCU4x.MCSS input. 0 _B Shadow transfer can only be requested by SW 1 _B Shadow transfer can be requested via SW and via the CCU4x.MCSS input. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|---------|------|--|
| MSE1 | 11 | rw | <p>Slice 1 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 1 can be requested not only by SW but also via the CCU4x.MCSS input.</p> <p>0_B Shadow transfer can only be requested by SW 1_B Shadow transfer can be requested via SW and via the CCU4x.MCSS input.</p> |
| MSE2 | 12 | rw | <p>Slice 2 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 2 can be requested not only by SW but also via the CCU4x.MCSS input.</p> <p>0_B Shadow transfer can only be requested by SW 1_B Shadow transfer can be requested via SW and via the CCU4x.MCSS input.</p> |
| MSE3 | 13 | rw | <p>Slice 3 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 3 can be requested not only by SW but also via the CCU4x.MCSS input.</p> <p>0_B Shadow transfer can only be requested by SW 1_B Shadow transfer can be requested via SW and via the CCU4x.MCSS input.</p> |
| MSDE | [15:14] | rw | <p>Multi Channel shadow transfer request configuration This field configures the type of shadow transfer requested via the CCU4x.MCSS input. The field CC4yTC.MSEy needs to be set in order for this configuration to have any effect.</p> <p>00_B Only the shadow transfer for period and compare values is requested 01_B Shadow transfer for the compare, period and prescaler compare values is requested 10_B Reserved 11_B Shadow transfer for the compare, period, prescaler and dither compare values is requested</p> |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|----------------------|------|---|
| 0 | 3, [7:6], [31:16] | r | Reserved A read always returns 0. |

GSTAT

The register contains the status of the prescaler and each timer slice (idle mode or running).

GSTAT

Global Status Register

(0004_H)

Reset Value: 000000F_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|-----|----|----|----|----|-----|-----|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| r | | | | | | | rh | r | | | | r | r | r | r |

| Field | Bits | Type | Description |
|------------|------|------|--|
| S0I | 0 | r | CC40 IDLE status This bit indicates if the CC40 slice is in IDLE mode or not. In IDLE mode the clocks for the CC40 slice are stopped. 0 _B Running 1 _B Idle |
| S1I | 1 | r | CC41 IDLE status This bit indicates if the CC41 slice is in IDLE mode or not. In IDLE mode the clocks for the CC41 slice are stopped. 0 _B Running 1 _B Idle |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|------------|------------------|------|--|
| S2I | 2 | r | CC42 IDLE status This bit indicates if the CC42 slice is in IDLE mode or not. In IDLE mode the clocks for the CC42 slice are stopped. 0_B Running 1_B Idle |
| S3I | 3 | r | CC43 IDLE status This bit indicates if the CC43 slice is in IDLE mode or not. In IDLE mode the clocks for the CC43 slice are stopped. 0_B Running 1_B Idle |
| PRB | 8 | rh | Prescaler Run Bit 0_B Prescaler is stopped 1_B Prescaler is running |
| 0 | [7:4], [31:9] | r | Reserved Read always returns 0. |

GIDLS

Through this register one can set the prescaler and the specific timer slices into idle mode.

GIDLS

Global Idle Set (0008_H) Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|------|----------|----|----|----|----|------|------|------|------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| r | | | | | | w | w | r | | | | w | w | w | w |

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| SS0I | 0 | w | CC40 IDLE mode set Writing a 1 _B to this bit sets the CC40 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| SS1I | 1 | w | CC41 IDLE mode set Writing a 1 _B to this bit sets the CC41 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| SS2I | 2 | w | CC42 IDLE mode set Writing a 1 _B to this bit sets the CC42 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| SS3I | 3 | w | CC43 IDLE mode set Writing a 1 _B to this bit sets the CC43 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| CPRB | 8 | w | Prescaler Run Bit Clear Writing a 1 _B into this register clears the Run Bit of the prescaler. Prescaler internal registers are not cleared. A read always returns 0. |
| PSIC | 9 | w | Prescaler clear Writing a 1 _B to this register clears the prescaler counter. It also loads the PSIV into the PVAL field for all Timer Slices. This performs a re alignment of the timer clock for all Slices. The Run Bit of the prescaler is not cleared. A read always returns 0. |
| 0 | [7:4], [31:10] | r | Reserved Read always returns 0. |

Capture/Compare Unit 4 (CCU4)

GIDLC

Through this register one can remove the prescaler and the specific timer slices from idle mode.

GIDLC

Global Idle Clear

(000C_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|------------------|------|---|
| CS0I | 0 | w | CC40 IDLE mode clear Writing a 1 _B to this bit removes the CC40 from IDLE mode. A read access always returns 0. |
| CS1I | 1 | w | CC41 IDLE mode clear Writing a 1 _B to this bit removes the CC41 from IDLE mode. A read access always returns 0. |
| CS2I | 2 | w | CC42 IDLE mode clear Writing a 1 _B to this bit removes the CC42 from IDLE mode. A read access always returns 0. |
| CS3I | 3 | w | CC43 IDLE mode clear Writing a 1 _B to this bit removes the CC43 from IDLE mode. A read access always returns 0. |
| SPRB | 8 | w | Prescaler Run Bit Set Writing a 1 _B into this register sets the Run Bit of the prescaler. A read always returns 0. |
| 0 | [7:4], [31:9] | r | Reserved Read always returns 0. |

GCSS

Through this register one can request a shadow transfer for the specific timer slice(s) and set the status bit for each of the compare channels.

GCSS

Global Channel Set

(0010_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|--------------|------|------|--|
| S0SE | 0 | w | Slice 0 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S0SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S0DSE | 1 | w | Slice 0 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S0DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |
| S0PSE | 2 | w | Slice 0 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S0PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S1SE | 4 | w | Slice 1 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S1SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S1DSE | 5 | w | Slice 1 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S1DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| S1PSE | 6 | w | Slice 1 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S1PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S2SE | 8 | w | Slice 2 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S2SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S2DSE | 9 | w | Slice 2 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S2DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |
| S2PSE | 10 | w | Slice 2 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S2PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S3SE | 12 | w | Slice 3 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S3SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S3DSE | 13 | w | Slice 3 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S3DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |
| S3PSE | 14 | w | Slice 3 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S3PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S0STS | 16 | w | Slice 0 status bit set Writing a 1 _B into this field sets the status bit of slice 0 (GCST.CC40ST) to 1 _B . A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-----------------------------|------|---|
| S1STS | 17 | w | Slice 1 status bit set Writing a 1 _B into this field sets the status bit of slice 1 (GCST.CC41ST) to 1 _B . A read always returns 0. |
| S2STS | 18 | w | Slice 2 status bit set Writing a 1 _B into this field sets the status bit of slice 2 (GCST.CC42ST) to 1 _B . A read always returns 0. |
| S3STS | 19 | w | Slice 3 status bit set Writing a 1 _B into this field sets the status bit of slice 3 (GCST.CC43ST) to 1 _B . A read always returns 0. |
| 0 | 3, 7, 11, 15, [31:20] | r | Reserved Read always returns 0. |

GCSC

Through this register one can reset a shadow transfer request for the specific timer slice and clear the status bit for each the compare channels.

GCSC

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| S0SC | 0 | w | Slice 0 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S0SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S0DSC | 1 | w | Slice 0 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S0DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S0PSC | 2 | w | Slice 0 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S0PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S1SC | 4 | w | Slice 1 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S1SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S1DSC | 5 | w | Slice 1 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S1DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S1PSC | 6 | w | Slice 1 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S1PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S2SC | 8 | w | Slice 2 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S2SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| S2DSC | 9 | w | Slice 2 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S2DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S2PSC | 10 | w | Slice 2 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S2PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S3SC | 12 | w | Slice 3 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S3SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S3DSC | 13 | w | Slice 3 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S3DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S3PSC | 14 | w | Slice 3 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S3PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S0STC | 16 | w | Slice 0 status bit clear Writing a 1 _B into this field clears the status bit of slice 0 (GCST.CC40ST) to 0 _B . A read always returns 0. |
| S1STC | 17 | w | Slice 1 status bit clear Writing a 1 _B into this field clears the status bit of slice 1 (GCST.CC41ST) to 0 _B . A read always returns 0. |
| S2STC | 18 | w | Slice 2 status bit clear Writing a 1 _B into this field clears the status bit of slice 2 (GCST.CC42ST) to 0 _B . A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-----------------------------|------|---|
| S3STC | 19 | w | Slice 3 status bit clear Writing a 1 _B into this field clears the status bit of slice 3 (GCST.CC43ST) to 0 _B . A read always returns 0. |
| 0 | 3, 7, 11, 15, [31:20] | r | Reserved Read always returns 0. |

GCST

This register holds the information of the shadow transfer requests and of each timer slice status bit.

GCST

Global Channel Status

(0018_H)

Reset Value: 00000000_H

| 0 | 3, 7, 11, 15, [31:20] | r | Reserved Read always returns 0. |

MIDR

This register contains the module identification number.

MIDR

Module Identification

(0080_H)

Reset Value: 00A6C0XX_H

| Field | Bits | Type | Description |
|-------------|---------|------|--|
| MODR | [7:0] | r | Module Revision This bit field indicates the revision number of the module implementation (depending on the design step). The given value of 00 _H is a placeholder for the actual number. |
| MODT | [15:8] | r | Module Type |
| MODN | [31:16] | r | Module Number |

17.7.2 Slice (CC4y) Registers

CC4yINS

The register contains the configuration for the input selector.

CC4yINS (y = 0 - 3)

Input Selector Configuration

(0100_H + 0100_H * y)

Reset Value: 00000000_H

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| EV0IS | [3:0] | rw | Event 0 signal selection This field selects which pins is used for the event 0. 0000 _B CCU4x.INyA 0001 _B CCU4x.INyB 0010 _B CCU4x.INyC 0011 _B CCU4x.INyD 0100 _B CCU4x.INyE 0101 _B CCU4x.INyF 0110 _B CCU4x.INyG 0111 _B CCU4x.INyH 1000 _B CCU4x.INyI 1001 _B CCU4x.INyJ 1010 _B CCU4x.INyK 1011 _B CCU4x.INyL 1100 _B CCU4x.INyM 1101 _B CCU4x.INyN 1110 _B CCU4x.INyO 1111 _B CCU4x.INyP |
| EV1IS | [7:4] | rw | Event 1 signal selection Same as EV0IS description |
| EV2IS | [11:8] | rw | Event 2 signal selection Same as EV0IS description |

| Field | Bits | Type | Description |
|-------|-------|------|---|
| STRTS | [1:0] | rw | External Start Functionality Selector Selects the Event that is going to be linked with the external start functionality. 00 _B External Start Function deactivated 01 _B External Start Function triggered by Event 0 10 _B External Start Function triggered by Event 1 11 _B External Start Function triggered by Event 2 |
| ENDS | [3:2] | rw | External Stop Functionality Selector Selects the Event that is going to be linked with the external stop functionality. 00 _B External Stop Function deactivated 01 _B External Stop Function triggered by Event 0 10 _B External Stop Function triggered by Event 1 11 _B External Stop Function triggered by Event 2 |
| CAP0S | [5:4] | rw | External Capture 0 Functionality Selector Selects the Event that is going to be linked with the external capture for capture registers number 1 and 0. 00 _B External Capture 0 Function deactivated 01 _B External Capture 0 Function triggered by Event 0 10 _B External Capture 0 Function triggered by Event 1 11 _B External Capture 0 Function triggered by Event 2 |
| CAP1S | [7:6] | rw | External Capture 1 Functionality Selector Selects the Event that is going to be linked with the external capture for capture registers number 3 and 2. 00 _B External Capture 1 Function deactivated 01 _B External Capture 1 Function triggered by Event 0 10 _B External Capture 1 Function triggered by Event 1 11 _B External Capture 1 Function triggered by Event 2 |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|---------|------|--|
| GATES | [9:8] | rw | External Gate Functionality Selector Selects the Event that is going to be linked with the counter gating function. This function is used to gate the timer increment/decrement procedure. 00 _B External Gating Function deactivated 01 _B External Gating Function triggered by Event 0 10 _B External Gating Function triggered by Event 1 11 _B External Gating Function triggered by Event 2 |
| UDS | [11:10] | rw | External Up/Down Functionality Selector Selects the Event that is going to be linked with the Up/Down counting direction control. 00 _B External Up/Down Function deactivated 01 _B External Up/Down Function triggered by Event 0 10 _B External Up/Down Function triggered by Event 1 11 _B External Up/Down Function triggered by Event 2 |
| LDS | [13:12] | rw | External Timer Load Functionality Selector Selects the Event that is going to be linked with the timer load function. 00 _B - External Load Function deactivated 01 _B - External Load Function triggered by Event 0 10 _B - External Load Function triggered by Event 1 11 _B - External Load Function triggered by Event 2 |
| CNTS | [15:14] | rw | External Count Selector Selects the Event that is going to be linked with the count function. The counter is going to be increment/decremented each time that a specific transition on the event is detected. 00 _B External Count Function deactivated 01 _B External Count Function triggered by Event 0 10 _B External Count Function triggered by Event 1 11 _B External Count Function triggered by Event 2 |
| OFS | 16 | rw | Override Function Selector This field enables the ST bit override functionality. 0 _B Override functionality disabled 1 _B Status bit trigger override connected to Event 1; Status bit value override connected to Event 2 |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| TS | 17 | rw | Trap Function Selector This field enables the trap functionality. 0_B Trap function disabled 1_B TRAP function connected to Event 2 |
| MOS | [19:18] | rw | External Modulation Functionality Selector Selects the Event that is going to be linked with the external modulation function. 00_B - Modulation Function deactivated 01_B - Modulation Function triggered by Event 0 10_B - Modulation Function triggered by Event 1 11_B - Modulation Function triggered by Event 2 |
| TCE | 20 | rw | Timer Concatenation Enable This bit enables the timer concatenation with the previous slice. 0_B Timer concatenation is disabled 1_B Timer concatenation is enabled <i>Note: In CC40 this field doesn't exist. This is a read only reserved field. Read access always returns 0.</i> |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yTCST

The register holds the status of the timer (running/stopped) and the information about the counting direction (up/down).

CC4yTCST (y = 0 - 3)

Slice Timer Status $(0108_H + 0100_H * y)$ **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 0 | | | | | | | | | | | | | | CDIR | TRB |
| r | | | | | | | | | | | | | | rh | rh |

| Field | Bits | Type | Description |
|-------|--------|------|--|
| TRB | 0 | rh | Timer Run Bit This field indicates if the timer is running. 0 _B Timer is stopped 1 _B Timer is running |
| CDIR | 1 | rh | Timer Counting Direction This field indicates if the timer is being increment or decremented 0 _B Timer is counting up 1 _B Timer is counting down |
| 0 | [31:2] | r | Reserved Read always returns 0 |

CC4yTCSET

Through this register it is possible to start the timer.

CC4yTCSET (y = 0 - 3)

Slice Timer Run Set (010C_H + 0100_H * y) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TRBS | 0 | w | Timer Run Bit set Writing a 1 _B into this field sets the run bit of the timer. Read always returns 0. |
| 0 | [31:1] | r | Reserved Read always returns 0 |

CC4yTCCLR

Through this register it is possible to stop and clear the timer, and clearing also the dither counter

CC4yTCCLR (y = 0 - 3)

Slice Timer Clear

(0110_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TRBC | 0 | w | Timer Run Bit Clear Writing a 1 _B into this field clears the run bit of the timer. The timer is not cleared. Read always returns 0. |
| TCC | 1 | w | Timer Clear Writing a 1 _B into this field clears the timer to 0000 _H . Read always returns 0. |
| DITC | 2 | w | Dither Counter Clear Writing a 1 _B into this field clears the dither counter to 0 _H . Read always returns 0. |
| 0 | [31:3] | r | Reserved Read always returns 0 |

CC4yTC

This register holds the several possible configurations for the timer operation.

Capture/Compare Unit 4 (CCU4)

CC4yTC (y = 0 - 3)

Slice Timer Control

(0114_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|-----|-------|----|-----|-----|----------|----------|-----|-----|-----------|-----------|-----|----------|----------|-----------|-----|

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| DIM | DITHE | | CCS | SCE | STR M | ENDM | | 0 | CAPC | | ECM | CMO D | CLS T | TSS M | TCM |
| rw | rw | | rw | rw | rw | rw | | r | rw | | rw | rh | rw | rw | rw |

| Field | Bits | Type | Description |
|-------|------|------|---|
| TCM | 0 | rw | Timer Counting Mode This field controls the actual counting scheme of the timer. 0 _B Edge aligned mode 1 _B Center aligned mode <i>Note: When using an external signal to control the counting direction, the counting scheme is always edge aligned.</i> |
| TSSM | 1 | rw | Timer Single Shot Mode This field controls the single shot mode. This is applicable in edge and center aligned modes. 0 _B Single shot mode is disabled 1 _B Single shot mode is enabled |
| CLST | 2 | rw | Shadow Transfer on Clear Setting this bit to 1 _B enables a shadow transfer when a timer clearing action is performed. Notice that the shadow transfer enable bitfields on the GCST register still need to be set to 1 _B via software. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------|------|---|
| CMOD | 3 | rh | Capture Compare Mode This field indicates in which mode the slice is operating. The default value is compare mode. The capture mode is automatically set by the HW when an external signal is mapped to a capture trigger. 0 _B Compare Mode 1 _B Capture Mode |
| ECM | 4 | rw | Extended Capture Mode This field control the Capture mode of the specific slice. It only has effect if the CMOD bit is 1 _B . 0 _B Normal Capture Mode. Clear of the Full Flag of each capture register is done by accessing the registers individually only. 1 _B Extended Capture Mode. Clear of the Full Flag of each capture register is done not only by accessing the individual registers but also by accessing the ECRD register. When reading the ECRD register, only the capture register register full flag pointed by the ECRD.VPTR is cleared. |
| CAPC | [6:5] | rw | Clear on Capture Control 00 _B Timer is never cleared on a capture event 01 _B Timer is cleared on a capture event into capture registers 2 and 3. (When SCE = 1 _B , Timer is always cleared in a capture event) 10 _B Timer is cleared on a capture event into capture registers 0 and 1. (When SCE = 1 _B , Timer is always cleared in a capture event) 11 _B Timer is always cleared in a capture event. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------|------|--|
| ENDM | [9:8] | rw | Extended Stop Function Control This field controls the extended functions of the external Stop signal. 00 _B Clears the timer run bit only (default stop) 01 _B Clears the timer only (flush) 10 _B Clears the timer and run bit (flush/stop) 11 _B Reserved <i>Note: When using an external up/down signal the flush operation sets the timer with zero if the counter is counting up and with the Period value if the counter is being decremented.</i> |
| STRM | 10 | rw | Extended Start Function Control This field controls the extended functions of the external Start signal. 0 _B Sets run bit only (default start) 1 _B Clears the timer and sets run bit (flush/start) <i>Note: When using an external up/down signal the flush operation sets the timer with zero if the counter is being incremented and with the Period value if the counter is being decremented.</i> |
| SCE | 11 | rw | Equal Capture Event enable 0 _B Capture into CC4yC0V/CC4yC1V registers control by CCycapt0 and capture into CC4yC3V/CC4yC2V control by CCycapt1 1 _B Capture into CC4yC0V/CC4yC1V and CC4yC3V/CC4yC2V control by CCycapt1 |
| CCS | 12 | rw | Continuous Capture Enable 0 _B The capture into a specific capture register is done with the rules linked with the full flags, described at Section 17.2.7.6 . 1 _B The capture into the capture registers is always done regardless of the full flag status (even if the register has not been read back). |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| DITHE | [14:13] | rw | Dither Enable This field controls the dither mode for the slice. See Section 17.2.10 . 00 _B Dither is disabled 01 _B Dither is applied to the Period 10 _B Dither is applied to the Compare 11 _B Dither is applied to the Period and Compare |
| DIM | 15 | rw | Dither input selector This fields selects if the dither control signal is connected to the dither logic of the specific slice of is connected to the dither logic of slice 0. Notice that even if this field is set to 1 _B , the field DITHE still needs to be programmed. 0 _B Slice is using its own dither unit 1 _B Slice is connected to the dither unit of slice 0. |
| FPE | 16 | rw | Floating Prescaler enable Setting this bit to 1 _B enables the floating prescaler mode. 0 _B Floating prescaler mode is disabled 1 _B Floating prescaler mode is enabled |
| TRAPE | 17 | rw | TRAP enable Setting this bit to 1 _B enables the TRAP action at the output pin. After mapping an external signal to the TRAP functionality, the user must set this field to 1 _B to activate the effect of the TRAP on the output pin. Writing a 0 _B into this field disables the effect of the TRAP function regardless of the state of the input signal. 0 _B TRAP functionality has no effect on the output 1 _B TRAP functionality affects the output |
| TRPSE | 21 | rw | TRAP Synchronization Enable Writing a 1 _B into this bit enables a synchronous exiting with the PWM signal of the trap state. 0 _B Exiting from TRAP state isn't synchronized with the PWM signal 1 _B Exiting from TRAP state is synchronized with the PWM signal |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------------|------|---|
| TRPSW | 22 | rw | TRAP State Clear Control 0_B The slice exits the TRAP state automatically when the TRAP condition is not present 1_B The TRAP state can only be exited by a SW request. |
| EMS | 23 | rw | External Modulation Synchronization Setting this bit to 1_B enables the synchronization of the external modulation functionality with the PWM period. 0_B External Modulation functionality is not synchronized with the PWM signal 1_B External Modulation functionality is synchronized with the PWM signal |
| EMT | 24 | rw | External Modulation Type This field selects if the external modulation event is clearing the CC4yST bit or if is gating the outputs. 0_B External Modulation functionality is clearing the CC4yST bit. 1_B External Modulation functionality is gating the outputs. |
| MCME | 25 | rw | Multi Channel Mode Enable 0_B Multi Channel Mode is disabled 1_B Multi Channel Mode is enabled |
| 0 | 7, [20:18] , [31:26] | r | Reserved Read always returns 0 |

CC4yPSL

This register holds the configuration for the output passive level control.

Capture/Compare Unit 4 (CCU4)

CC4yPSL (y = 0 - 3)

Passive Level Config

(0118_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| PSL | 0 | rw | Output Passive Level This field controls the passive level of the output pin. 0 _B Passive Level is LOW 1 _B Passive Level is HIGH A write always addresses the shadow register, while a read always returns the current used value. |
| 0 | [31:1] | r | Reserved A read access always returns 0 |

CC4yDIT

This register holds the current dither compare and dither counter values.

CC4yDIT (y = 0 - 3)

Dither Config

(011C_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| DCV | [3:0] | rh | Dither compare Value This field contains the value used for the dither comparison. This value is updated when a shadow transfer occurs with the CC4yDITS.DCVS . |
| DCNT | [11:8] | rh | Dither counter actual value |
| 0 | [7:4], [31:12] | r | Reserved Read always returns 0. |

CC4yDITS

This register contains the value that is going to be loaded into the **CC4yDIT.DCV** when the next shadow transfer occurs.

CC4yDITS (y = 0 - 3)

Dither Shadow Register **(0120_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| DCVS | [3:0] | rw | Dither Shadow Compare Value This field contains the value that is going to be set on the dither compare value, CC4yDIT.DCV , within the next shadow transfer. |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC4yPSC

This register contains the value that is loaded into the prescaler during restart.

Capture/Compare Unit 4 (CCU4)

CC4yPSC (y = 0 - 3)

Prescaler Control (0124_H + 0100_H * y) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| PSIV | [3:0] | rw | Prescaler Initial Value This field contains the value that is applied to the Prescaler at startup. When floating prescaler mode is used, this value is applied when a timer compare match AND prescaler compare match occurs or when a capture event is triggered. |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC4yFPC

This register contains the value used for the floating prescaler compare and the actual prescaler division value.

Capture/Compare Unit 4 (CCU4)

CC4yFPC (y = 0 - 3)

Floating Prescaler Control **(0128_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|-------------------------------|------|--|
| PCMP | [3:0] | rh | Floating Prescaler Compare Value This field contains comparison value used in floating prescaler mode. The comparison is triggered by the Timer Compare match event. See Section 17.2.11.2 . |
| PVAL | [11:8] | rwh | Actual Prescaler Value See Table 17-7 . Writing into this register is only possible when the prescaler is stopped. When the floating prescaler mode is not used, this value is equal to the CC4yPSC.PSIV . |
| 0 | [7:4], [15:12], [31:16] | r | Reserved Read always returns 0. |

CC4yFPCS

This register contains the value that is going to be transferred to the [CC4yFPC.PCMP](#) field within the next shadow transfer update.

Capture/Compare Unit 4 (CCU4)

CC4yFPCS (y = 0 - 3)

Floating Prescaler Shadow **(012C_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| PCMP | [3:0] | rw | Floating Prescaler Shadow Compare Value This field contains the value that is going to be set on the CC4yFPC .PCMP within the next shadow transfer. See Table 17-7 . |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC4yPR

This register contains the actual value for the timer period.

CC4yPR (y = 0 - 3)

Timer Period Value **(0130_H + 0100_H * y)** **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-----------|---------|------|---|
| PR | [15:0] | rh | Period Register Contains the value of the timer period. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 2 and 3, PR is not accessible for writing. A read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yPRS

This register contains the value for the timer period that is going to be transferred into the **CC4yPR.PR** field when the next shadow transfer occurs.

CC4yPRS (y = 0 - 3)

Timer Shadow Period Value **(0134_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| PRS | [15:0] | rw | Period Register Contains the value of the timer period, that is going to be passed into the CC4yPR.PR field when the next shadow transfer occurs. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 2 and 3, the PRS is not accessible for writing. A read always returns 0.</i> |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|----------|---------|------|---|
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yCR

This register contains the value for the timer comparison.

CC4yCR (y = 0 - 3)

Timer Compare Value **(0138_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-----------|---------|------|---|
| CR | [15:0] | rh | Compare Register Contains the value for the timer comparison. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 0 and 1, a read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yCRS

This register contains the value that is going to be loaded into the **CC4yCR.CR** field when the next shadow transfer occurs.

Capture/Compare Unit 4 (CCU4)

CC4yCRS (y = 0 - 3)

Timer Shadow Compare Value ($013C_H + 0100_H * y$)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| CRS | [15:0] | rw | Compare Register Contains the value for the timer comparison, that is going to be passed into the CC4yCR.CR field when the next shadow transfer occurs. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 0 and 1, a read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yTIMER

This register contains the current value of the timer.

Capture/Compare Unit 4 (CCU4)

CC4yTIMER (y = 0 - 3)

Timer Value $(0170_H + 0100_H * y)$ **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|---------|------|--|
| TVAL | [15:0] | rwh | Timer Value This field contains the actual value of the timer. A write access is only possible when the timer is stopped. |
| 0 | [31:16] | r | Reserved A read access always returns 0 |

CC4yC0V

This register contains the values associated with the Capture 0 field.

CC4yC0V (y = 0 - 3)

Capture Register 0 $(0174_H + 0100_H * y)$ **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| CAPTV | [15:0] | rh | Capture Value This field contains the capture register 0 value. See Figure 17-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 0. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 0 after the last read access. See Figure 17-26 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yC1V

This register contains the values associated with the Capture 1 field.

CC4yC1V (y = 0 - 3)

Capture Register 1 (0178_H + 0100_H * y) **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPT | [15:0] | rh | Capture Value This field contains the capture register 1 value. See Figure 17-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 1. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 1 after the last read access. See Figure 17-26 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yC2V

This register contains the values associated with the Capture 2 field.

CC4yC2V (y = 0 - 3)

Capture Register 2 ($017C_H + 0100_H * y$) **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| CAPTV | [15:0] | rh | Capture Value This field contains the capture register 2 value. See Figure 17-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 2. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 2 after the last read access. See Figure 17-26 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yC3V

This register contains the values associated with the Capture 3 field.

CC4yC3V (y = 0 - 3)

Capture Register 3 (0180_H + 0100_H * y) **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPT | [15:0] | rh | Capture Value This field contains the capture register 3 value. See Figure 17-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 3. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 3 after the last read access. See Figure 17-26 . In compare mode a read access always returns 0. 0 _B No new value was captured into the specific capture register 1 _B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yINTS

This register contains the status of all interrupt sources.

CC4yINTS (y = 0 - 3)

Interrupt Status (01A0_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|------------|------------|------------|------------|----|----|----|----|------------|------------|------------|------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | TRP | E2A | E1A | E0A | 0 | | | | CMD | CMU | OMD | PMU |
| r | | | | rh | rh | rh | rh | r | | | | rh | rh | rh | rh |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|------|------|--|
| PMUS | 0 | rh | Period Match while Counting Up 0_B Period match while counting up not detected 1_B Period match while counting up detected |
| OMDS | 1 | rh | One Match while Counting Down 0_B One match while counting down not detected 1_B One match while counting down detected |
| CMUS | 2 | rh | Compare Match while Counting Up 0_B Compare match while counting up not detected 1_B Compare match while counting up detected |
| CMDS | 3 | rh | Compare Match while Counting Down 0_B Compare match while counting down not detected 1_B Compare match while counting down detected |
| E0AS | 8 | rh | Event 0 Detection Status Depending on the user selection on the CC4yINS.EV0EM , this bit can be set when a rising, falling or both transitions are detected. 0_B Event 0 not detected 1_B Event 0 detected |
| E1AS | 9 | rh | Event 1 Detection Status Depending on the user selection on the CC4yINS.EV1EM , this bit can be set when a rising, falling or both transitions are detected. 0_B Event 1 not detected 1_B Event 1 detected |
| E2AS | 10 | rh | Event 2 Detection Status Depending on the user selection on the CC4yINS.EV1EM , this bit can be set when a rising, falling or both transitions are detected. 0_B Event 2 not detected 1_B Event 2 detected <i>Note: If this event is linked with the TRAP function, this field is automatically cleared when the slice exits the Trap State.</i> |
| TRPF | 11 | rh | Trap Flag Status This field contains the status of the Trap Flag. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| 0 | [7:4], [31:12] | r | Reserved A read always returns 0. |

CC4yINTE

Through this register it is possible to enable or disable the specific interrupt source(s).

CC4yINTE (y = 0 - 3)

Interrupt Enable Control (01A4_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----------|----------|----------|----|----|----|----|----------|----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | E2A E | E1A E | E0A E | 0 | | | | CMD E | CMU E | OME | PME |
| r | | | | | rw | rw | rw | r | | | | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|-------|------|------|--|
| PME | 0 | rw | Period match while counting up enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time a period match while counting up occurs. 0 _B Period Match interrupt is disabled 1 _B Period Match interrupt is enabled |
| OME | 1 | rw | One match while counting down enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time an one match while counting down occurs. 0 _B One Match interrupt is disabled 1 _B One Match interrupt is enabled |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|-------------------|------|--|
| CMUE | 2 | rw | Compare match while counting up enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time a compare match while counting up occurs. 0 _B Compare Match while counting up interrupt is disabled 1 _B Compare Match while counting up interrupt is enabled |
| CMDE | 3 | rw | Compare match while counting down enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time a compare match while counting down occurs. 0 _B Compare Match while counting down interrupt is disabled 1 _B Compare Match while counting down interrupt is enabled |
| E0AE | 8 | rw | Event 0 interrupt enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time that Event 0 is detected. 0 _B Event 0 detection interrupt is disabled 1 _B Event 0 detection interrupt is enabled |
| E1AE | 9 | rw | Event 1 interrupt enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time that Event 1 is detected. 0 _B Event 1 detection interrupt is disabled 1 _B Event 1 detection interrupt is enabled |
| E2AE | 10 | rw | Event 2 interrupt enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time that Event 2 is detected. 0 _B Event 2 detection interrupt is disabled 1 _B Event 2 detection interrupt is enabled |
| 0 | [7:4], [31:11] | r | Reserved A read always returns 0 |

CC4ySRS

Through this register it is possible to select to which service request line each interrupt source is forwarded.

Capture/Compare Unit 4 (CCU4)

CC4ySRS (y = 0 - 3)

Service Request Selector

(01A8_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|------|----|------|----|------|----|----|----|----|----|------|----|------|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |

| r | | rw | | rw | | rw | | r | | | | rw | | rw | |

| Field | Bits | Type | Description |
|-------------|-------|------|---|
| POSR | [1:0] | rw | Period/One match Service request selector This field selects to which slice Service request line, the interrupt(s) generated by the Period match while counting up and One match while counting down are going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| CMSR | [3:2] | rw | Compare match Service request selector This field selects to which slice Service request line, the interrupt(s) generated by the Compare match while counting up and Compare match while counting down are going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| E0SR | [9:8] | rw | Event 0 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 0 detection is going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| E1SR | [11:10] | rw | Event 1 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 1 detection is going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| E2SR | [13:12] | rw | Event 2 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 2 detection is going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| 0 | [7:4], [31:14] | r | Reserved Read always returns 0. |

CC4ySWS

Through this register it is possible for the SW to set a specific interrupt status flag.

CC4ySWS (y = 0 - 3)

Interrupt Status Set (01AC_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|-----------|----------|----------|----------|----|----|----|----|----------|----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | STR PF | SE2 A | SE1 A | SE0 A | 0 | | | | SCM D | SCM U | SOM | SPM |
| r | | | | w | w | w | w | r | | | | w | w | w | w |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| SPM | 0 | w | Period match while counting up set Writing a 1 _B into this field sets the CC4yINTS .PMUS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SOM | 1 | w | One match while counting down set Writing a 1 _B into this bit sets the CC4yINTS .OMDS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SCMU | 2 | w | Compare match while counting up set Writing a 1 _B into this field sets the CC4yINTS .CMUS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SCMD | 3 | w | Compare match while counting down set Writing a 1 _B into this bit sets the CC4yINTS .CMDS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE0A | 8 | w | Event 0 detection set Writing a 1 _B into this bit sets the CC4yINTS .E0AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE1A | 9 | w | Event 1 detection set Writing a 1 _B into this bit sets the CC4yINTS .E1AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE2A | 10 | w | Event 2 detection set Writing a 1 _B into this bit sets the CC4yINTS .E2AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| STRPF | 11 | w | Trap Flag status set Writing a 1 _B into this bit sets the CC4yINTS .TRPF bit. A read always returns 0. |
| 0 | [7:4], [31:12] | r | Reserved Read always returns 0 |

CC4ySWR

Through this register it is possible for the SW to clear a specific interrupt status flag.

Capture/Compare Unit 4 (CCU4)

CC4ySWR (y = 0 - 3)

Interrupt Status Clear

(01B0_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|-----------|----------|----------|----------|----|----|----|----|----------|----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |

| 0 | | | | RTR PF | RE2 A | RE1 A | RE0 A | 0 | | | | RCM D | RCM U | ROM | RPM |
| r | | | | w | w | w | w | r | | | | w | w | w | w |

| Field | Bits | Type | Description |
|-------|------|------|---|
| RPM | 0 | w | Period match while counting up clear Writing a 1 _B into this field clears the CC4yINTS .PMUS bit. A read always returns 0. |
| ROM | 1 | w | One match while counting down clear Writing a 1 _B into this bit clears the CC4yINTS .OMDS bit. A read always returns 0. |
| RCMU | 2 | w | Compare match while counting up clear Writing a 1 _B into this field clears the CC4yINTS .CMUS bit. A read always returns 0. |
| RCMD | 3 | w | Compare match while counting down clear Writing a 1 _B into this bit clears the CC4yINTS .CMDS bit. A read always returns 0. |
| RE0A | 8 | w | Event 0 detection clear Writing a 1 _B into this bit clears the CC4yINTS .E0AS bit. A read always returns 0. |
| RE1A | 9 | w | Event 1 detection clear Writing a 1 _B into this bit clears the CC4yINTS .E1AS bit. A read always returns 0. |
| RE2A | 10 | w | Event 2 detection clear Writing a 1 _B into this bit clears the CC4yINTS .E2AS bit. A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|--|
| RTRPF | 11 | w | Trap Flag status clear Writing a 1 _B into this bit clears the CC4yINTS .TRPF bit. Not valid if CC4yTC .TRPEN = 1 _B and the Trap State is still active. A read always returns 0. |
| 0 | [7:4], [31:12] | r | Reserved Read always returns 0 |

CC4yECRD0

Through this register it is possible to read back the FIFO structure of the capture function that is linked with the capture trigger 0. The read back is only valid if the **CC4yTC**.ECM = 1_B.

CC4yECRD0 (y = 0 - 3)

Extended Read Back 0 (01B8_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|------|----|----|----|----|----|-----|-----|------|------|------|----|----|----|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| CAPV | | | | | | | | | | | | | | | |
| rh | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|-------|---------|------|---|
| CAPV | [15:0] | rh | Timer Capture Value This field contains the timer captured value |
| FPCV | [19:16] | rh | Prescaler Capture value This field contains the value of the prescaler clock division associated with the specific CAPV field |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| SPTR | [21:20] | rh | Slice pointer This field indicates the slice index in which the value was captured. 00 _B CC40 01 _B CC41 10 _B CC42 11 _B CC43 |
| VPTR | [23:22] | rh | Capture register pointer This field indicates the capture register index in which the value was captured. 00 _B Capture register 0 01 _B Capture register 1 10 _B Capture register 2 11 _B Capture register 3 |
| FFL | 24 | rh | Full Flag This bit indicates if the associated capture register contains a new value. 0 _B No new value was captured into this register 1 _B A new value has been captured into this register |
| LCV | 25 | rh | Lost Capture Value This field indicates if between two reads of the ECRD0 a capture trigger occurred while the FIFO structure was full. If a capture trigger occurred between two reads than a capture value was lost. This field is automatically cleared by the HW whenever a read to the ECRD occurs. 0 _B No capture was lost 1 _B A capture was lost |
| 0 | [31:26] | r | Reserved Read always returns 0 |

CC4yECRD1

Through this register it is possible to read back the FIFO structure of the capture function that is linked with the capture trigger 1. The read back is only valid if the **CC4yTC.ECM** = 1_B.

Capture/Compare Unit 4 (CCU4)

CC4yECRD1 (y = 0 - 3)

Extended Read Back 1

(01BC_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |

| SPTR | [21:20] | rh | Slice pointer This field indicates the slice index in which the value was captured. 00 _B CC40 01 _B CC41 10 _B CC42 11 _B CC43 |
| VPTR | [23:22] | rh | Capture register pointer This field indicates the capture register index in which the value was captured. 00 _B Capture register 0 01 _B Capture register 1 10 _B Capture register 2 11 _B Capture register 3 |
| FFL | 24 | rh | Full Flag This bit indicates if the associated capture register contains a new value. 0 _B No new value was captured into this register 1 _B A new value has been captured into this register |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| LCV | 25 | rh | Lost Capture Value This field indicates if between two reads of the ECRD0 a capture trigger occurred while the FIFO structure was full. If a capture trigger occurred between two reads than a capture value was lost. This field is automatically cleared by the HW whenever a read to the ECRD occurs. 0 _B No capture was lost 1 _B A capture was lost |
| 0 | [31:26] | r | Reserved Read always returns 0 |

17.8 Interconnects

The tables that refer to the “global pins” are the ones that contain the inputs/outputs of each module that are common to all slices.

The GPIO connections are available at the Ports chapter.

17.8.1 CCU40 pins

Table 17-13 CCU40 Pin Connections

| Global Inputs/Outputs | I/O | Connected To | Description |
|-----------------------|-----|----------------------|---|
| CCU40.MCLK | I | PCLK | Kernel clock |
| CCU40.CLKA | I | not connected | another count source for the prescaler |
| CCU40.CLKB | I | ERU0.IOUT0 | another count source for the prescaler |
| CCU40.CLKC | I | ERU0.IOUT1 | another count source for the prescaler |

18 General Purpose I/O Ports (Ports)

The XMC1100 has 35 digital General Purpose Input/Output (GPIO) port lines which are connected to the on-chip peripheral units.

18.1 Overview

The Ports provide a generic and very flexible software and hardware interface for all standard digital I/Os. Each Port slice has individual interfaces for the operation as General Purpose I/O and it further provides the connectivity to the on-chip periphery and the control for the pad characteristics. [Table 18-1](#) gives an overview of the available PORTS and other pins in the different packages of the XMC1100:

Table 18-1 Port/Pin Overview

| Port | VQFN-40 | TSSOP-38 | VQFN-24 | TSSOP-16 | Note |
|-----------------------------------|---------|----------|---------|----------|--|
| P0 | 16 | 16 | 10 | 8 | Standard bi-directional pad |
| P1 | 7 | 6 | 4 | - | High current and Standard bi-directional pad |
| P2 | 12 | 12 | 8 | 6 | Analog/Digital input and bi-directional pad |
| Supply VDD, ADC Reference Voltage | 1 | 1 | 1 | 1 | VDD |
| Supply GND, ADC Reference Ground | 1 | 1 | 1 | 1 | VSS |
| I/O Port Supply | 1 | 1 | - | - | VDDP |
| I/O Port Ground | 1 | 1 | - | - | VSSP |

18.1.1 Features

This is a list of the main features of the Ports:

- same generic register interface for each port pin, [Chapter 18.8](#)
- simple and robust software access for general purpose I/O functionality, [Chapter 18.2](#)
- direct input connections to on-chip peripherals, [Chapter 18.2.1](#)
- dedicated hardware interface for CCU and USIC, [Chapter 18.3](#)
- defined power-up/power-fail behavior, [Chapter 18.6](#).

General Purpose I/O Ports (Ports)

- up to seven alternate output paths from peripherals selectable, [Chapter 18.8.1](#)
- programmable open-drain or push-pull output driver stage, [Chapter 18.8.1](#)
- programmable weak pull-up and pull-down devices, [Chapter 18.8.1](#)
- programmable input inverter, [Chapter 18.8.1](#)
- programmable pad hysteresis, [Chapter 18.8.2](#)
- disabling of digital input stage on shared analog inputs, [Chapter 18.8.3](#)
- separate set and clear output control to avoid read-modify-write operations, [Chapter 18.8.5](#)
- programmable power-save behavior in Deep-Sleep mode, [Chapter 18.8.7](#)
- Privileged Mode restricted access to configuration registers to avoid accidental modification

18.1.2 Block Diagram

Below is a figure with the generic structure of a digital port pin, split into the port slice with the control logic and the pad with the pull devices and the input and output stages, [Figure 18-1](#).

General Purpose I/O Ports (Ports)

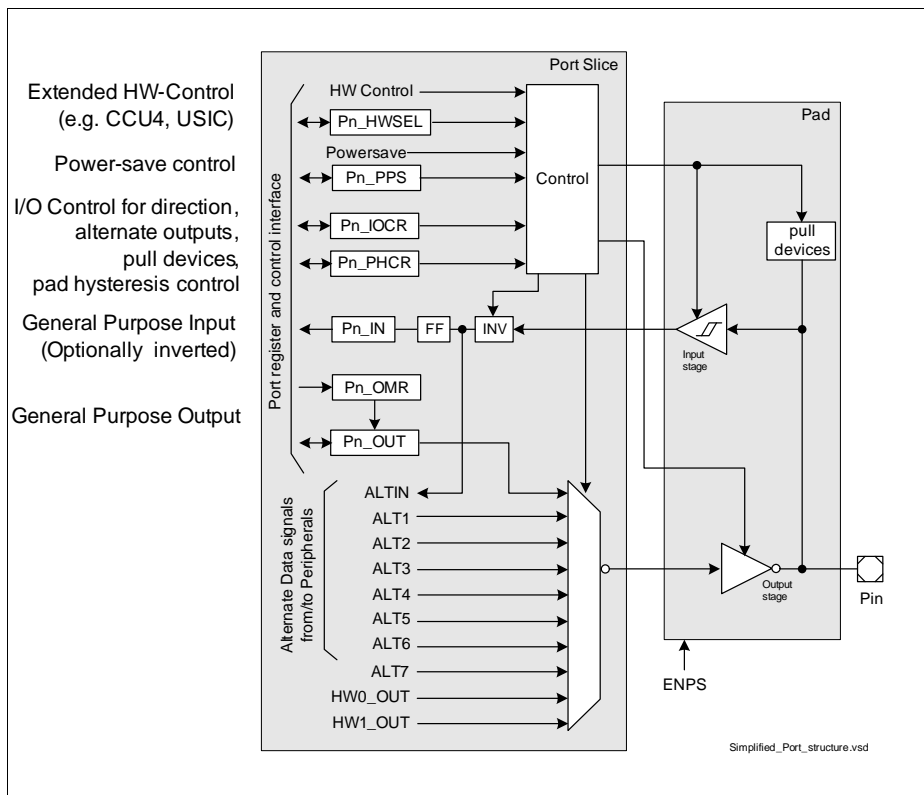

Figure 18-1 General Structure of a digital Port Pin

18.1.3 Definition of Terms

Some specific terms are used throughout this chapter:

- **Pin/Ball:** External connection of the device to the PCB.
- **Dedicated Pin:** A Pin with a dedicated function that is not under the control of the port logic (i.e. supply pins).
- **Port Pin:** A pin under the control of the port logic (P0.1).
- **Port:** A group of up to 16 Port Pins sharing the same generic register set (P0).
- **Port Slice:** The “sum” of register bits and control logic used to control a port pin.
- **Pad:** Analog component containing the output driver, pull devices and input Schmitt-Trigger. Also interfaces the internal logic operating on V_{DDC} to the pad supply domain V_{DDP} .

General Purpose I/O Ports (Ports)

- **GPIO:** General Purpose Input/Output. A port pin with the input and/or output function controlled by the application software.
- **Alternate Function:** Direct connection of a port pin with an on-chip peripheral.

18.2 GPIO and Alternate Functions

The Ports can be operated as General Purpose Input/Output (GPIO) and with Alternate Functions of the on-chip periphery, configured by the Port Input/Output Control Register (Pn_IOCR, [Chapter 18.8.1](#)). It selects between

- Direct or Inverted Input
 - with or without pull device
- Push-pull or Open-Drain Output driven by
 - Pn_OUT (GPIO)
 - selected peripheral output connections.

As GPIO the port pin is controlled by the application software, reading the input value by the Port Input register Pn_IN ([Chapter 18.8.6](#)) and/or defining the output value by the Output Modification Register Pn_OMR ([Chapter 18.8.5](#)). Output modification by Pn_OMR is preferred over the direct change of the output value with the Output register Pn_OUT ([Chapter 18.8.4](#)), as Pn_OMR allows the manipulation of individual port pins in a single access without “disturbing” other pins controlled by the same Pn_OUT register. If an application uses a GPIO as a bi-directional I/O line, register Pn_IOCR has to be written to switch between input and output functionality.

For the operation with Alternate Functions, the port pins are directly connected to input or output functions of the on-chip periphery. This allows the peripheral to directly evaluate the input value or drive the output value of the port pin without further application software interaction after the initial configuration. The connection of alternate functions is used for control and communication interfaces, like a PWM from a CAPCOM unit or a SPI communication of a USIC channel. A detailed connectivity list of the peripherals to the port pins is given in the [Port I/O Function Description](#) chapter. For specific functions, certain peripherals may also take direct control of “their” port pins, see [Hardware Controlled I/Os](#).

18.2.1 Input Operation

As an input, the actual voltage level at the port pin is translated into a logical 0_B or 1_B via a Schmitt-Trigger device within the pad. The resulting input value can be optionally inverted. As general purpose input, the signal is synchronized and can be read with the Input register (Pn_IN, [Chapter 18.8.6](#)). Alternatively, the input can be connected to the multiple on-chip peripherals via the ALTIN signal. Where necessary, these peripherals have internal controls to select the appropriate port pin with an input multiplexer stage, and will take care of synchronization and further processing of the input signals. (See respective peripheral chapters for more details on the input selection and handling). With the Pn_IOCR register ([Chapter 18.8.1](#)), it is also possible to activate an internal weak

pull-up or pull-down device in the pad.

The input register Pn_IN and ALTIN signal always represent the state of the input, independent whether the port pin is configured as input or output. This means that even if the port is in output mode, the level of the pin can be read by software via Pn_IN and/or a peripheral can use the pin level as an input.

Pad Hysteresis Control

The pad hysteresis can be configured according to the application needs via the Pad Hysteresis Control register (Pn_PHCR, [Chapter 18.8.2](#)). Selecting the appropriate pad hysteresis allows optimized pad oscillation behaviour for touch-sensing applications.

18.2.2 Output Operation

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. Switching between input and output mode is accomplished through the Pn_IOCRR register ([Chapter 18.8.1](#)), which

- enables or disables the output driver,
- selects between open-drain and push-pull mode,
- selects the general purpose or alternate function outputs.

The output multiplexer selects the signal source of the output with

- Pn_IOCRR
 - general purpose output (Pn_OUT, [Chapter 18.8.4](#))
 - alternate peripheral functions, ALT1...ALT7
- hardware control, Pn_HWSEL
 - HW0_OUT
 - HW1_OUT

Note: It is recommended to complete the Port and peripheral configuration with respect to operating mode and initial values before the port pin is switched to output mode.

The output function is exclusive, meaning that only one peripheral has control of the output path at any one time.

Used as general purpose output, software can directly modify the content of Pn_OUT to define the output value on the pin. A write operation to Pn_OUT updates all port pins of that port (e.g. P0) that are configured as general purpose output. Updating just one or a selected few general purpose output pins via Pn_OUT requires a masked read-modify-write operation to avoid disturbing pins that shall not be changed. Direct writes to Pn_OUT will also affect Pn_OUT bits configured for use with the Pin Power-save function, [Chapter 18.4](#).

Because of that, it is preferred to modify Pn_OUT bits by the Output Modification Register Pn_OMR ([Chapter 18.8.5](#)). The bits in Pn_OMR allow to individually set, clear or toggle the bits in the Pn_OUT register and only update the “addressed” Pn_OUT bits.

General Purpose I/O Ports (Ports)

The data written by software into the output register Pn_OUT can also be used as input data to an on-chip peripheral. This enables, for example, peripheral tests and simulation via software without external circuitry.

Output lines of on-chip peripherals can directly control the output value of the output driver if selected via ALT1 to ALT7 as well as HW0_OUT and HW1_OUT. After initialization, this allows the connected peripherals to directly drive complex control and communication patterns without further software interaction with the ports.

The actual logic level at the pin can be examined through reading Pn_IN and compared against the applied output level (either applied by the output register Pn_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the pin caused by external circuitry. In addition, software-supported arbitration schemes between different “masters” can be implemented in this way, using the open-drain configuration and an external wired-AND circuitry. Collisions on the external communication lines can be detected when a high level (1_B) is output, but a low level (0_B) is seen when reading the pin value via the input register Pn_IN or directly by a peripheral (via ALTIN, for example a USIC channel in IIC mode).

There are two pad types in XMC1100 providing different drive strength:

- Standard pad
- High Current pad

The assignment of each port pin to one of these pad types is listed in the Package Pin Summary table. Further details about pad properties are summarized in the Data Sheet.

18.3 Hardware Controlled I/Os

Some ports pins are overlaid with peripheral functions for which the connected peripheral needs direct hardware control, e.g. for the direction of a bi-directional data bus. There is a dedicated hardware control interface for these functions. As multiple peripherals need access to this interface, the Pn_HWSEL register ([Chapter 18.8.8](#)) allows to select between the hardware “masters”.

Depending on the operating mode, the peripheral can take control of various functions:

- Pin direction, input or output, e.g. for bi-directional signals
- Driver type, open-drain or push-pull
- Pull devices under peripheral control or under standard control via Pn_IOCR

Some configurations remain under control by the standard configuration interface, the pad hysteresis by Pn_PHCR and the direct or inverted input path by Pn_IOCR.

Pn_HWSEL.HWx just pre-assigns the hardware-control of the pin to a certain peripheral, but the peripheral itself decides when to take control over it. As long as the peripheral does not take control of a given pin via HWx_EN, the configuration of this pin is still defined by the configuration registers and it is available as GPIO or for other alternate functions. This might be because the selected peripheral has controls to just activate a subset of its pins, or because the peripheral is not active at all.

General Purpose I/O Ports (Ports)

This mechanism can also be used to prohibit the hardware control of certain pins to a peripheral, in case the application does not need the respective functionality and the peripheral has no controls to disable the hardware control selectively.

The default hardware input configuration and the pull devices are controlled by Pn_IOCR.

The outputs of CCU4 module can be used to control the internal pull devices via direct hardware control. A detailed connectivity list of the hardware I/O and pull control of the peripheral to the port pins is given in the **Hardware Controlled I/O Function Description** chapter.

Note: Do not enable the Pin Power Save function for pins configured for Hardware Control (Pn_HWSEL.HWx != 00_B). Doing so may result in an undefined behavior of the pin when the device enters the Deep Sleep state.

18.4 Power Saving Mode Operation

In Deep-Sleep mode, the behavior of a pin depends on the setting of the Pin Power save register (Pn_PPS, **Chapter 18.8.7**). Basically, each pin can be configured to react to the Power Save Mode Request or to ignore it. In case a pin is configured to react to a Power Save Mode Request, the output driver is switched to tri-state, the input Schmitt-Trigger and the pull devices are switched off (see **Figure 18-2**). The input signal to the on-chip peripherals is optionally driven statically high or low, software-defined by a value stored in Pn_OUT or by the last input value sampled to the Pn_OUT register during normal operation. The actual reaction is configured with the Pn_IOCR register under power save conditions, see **Table 18-8**.

General Purpose I/O Ports (Ports)

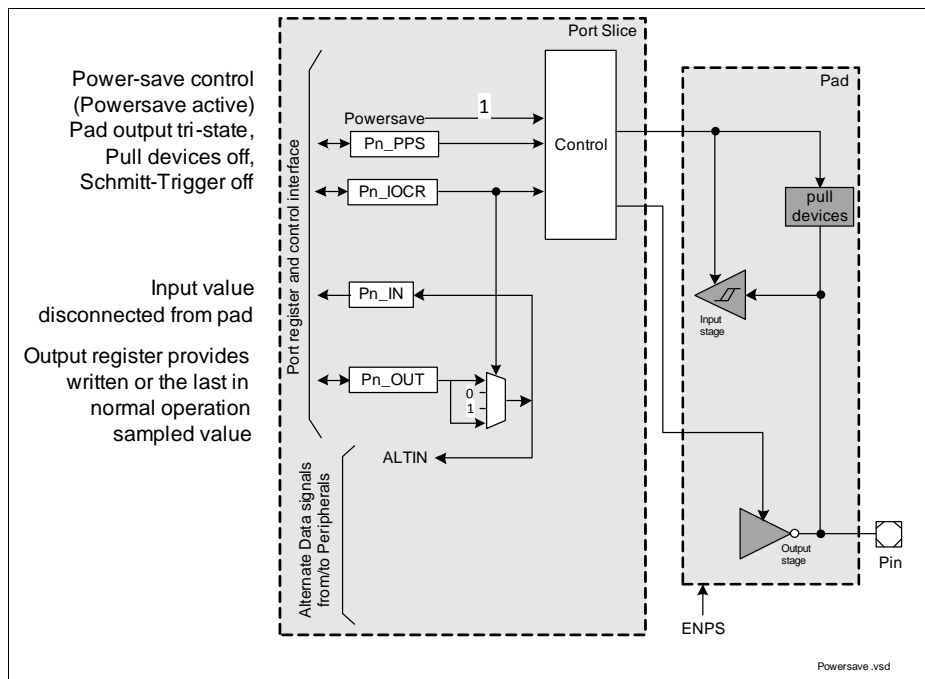

Figure 18-2 Port Pin in Power Save State

Note: Do not enable the Pin Power Save function for pins configured for Hardware Control ($Pn_HWSEL.HWx \neq 00_B$). Doing so may result in an undefined behavior of the pin when the device enters the Deep Sleep state.

18.5 Analog Ports

P2.2 - P2.9 is the analog and digital input port with a simplified port and pad structure, see [Figure 18-3](#). The analog pads have no output drivers and the digital input Schmitt-Trigger can be controlled by the Pn_PDISC ([Chapter 18.8.3](#)) register. Accordingly, the port control interface is reduced in its functionality. The Pn_IOCRR register controls the pull devices, the optional input inversion and the input source in power-save mode. The Pn_OUT has only its power-save functionality, as described in [Chapter 18.4](#).

Figure 18-3 Analog Port Structure

18.6 Power, Reset and Clock

All digital I/O pads are held in a defined state, tristate, with output driver disabled and no pull devices active when one of the following occurs:

- During power-up, until V_{DDC} and V_{DDP} voltage levels are stable and within limits
- During power-fail, one or more voltage levels are outside the limits

Refer to the EVR section in the SCU chapter and Data Sheet for details on the power-up, supply monitoring and voltage limits.

All Port registers are reset with the System Reset (see Reset Control Unit chapter in the System Control Unit). The standard reset values are defined such that the port pins are configured as tri-state inputs, output driver disabled and no pull devices active. Exceptions from these standard values are related to special interfaces or the analog input channels.

All registers of the Ports are clocked with f_{MCLK} .

18.7 Initialization and System Dependencies

It is recommended to follow pre-defined routines for the initialization of the port pins.

Input

When a peripheral shall use a port pin as input, the actual pin levels may immediately trigger an unexpected peripheral event (e.g. clock edge at SPI). This can be avoided by forcing the "passive" level via pull-up/down programming.

The following steps are required to configure a port pin as an input:

- Pn_IOCR
input configuration with pull device and/or power-save mode configuration
- Pn_PHCR
pad hysteresis configuration (if applicable)
- Hardware Control (if applicable)
 - Pn_HWSEL
switch hardware control to peripheral
- Pin Power Save (if applicable)
 - Pn_OMR/Pn_OUT
default value in power save mode (if applicable)
 - Pn_PPS
enable power save control

Output

When a port pin is configured as output for an on-chip peripheral, it is important that the peripheral is configured before the port switches the control to the peripheral in order to avoid spikes on the output.

The following steps are required to configure a port pin as an output:

- Pn_OMR/Pn_OUT
Initial output value (as general purpose output)
- GPIO or Alternate Output
 - Pn_IOCR
Output multiplexer select
Push-pull or open-drain output driver mode
Activates the output driver!
- Hardware Control
 - Pn_IOCR
depending on the hardware function Pn_IOCR can enable the internal pull devices
 - Pn_HWSEL
Switch hardware control to peripheral

Transitions

If a port pin is used for different functions that require a reconfiguration of the port registers, it is recommended to do this transition via an intermediate “neutral” tri-state input configuration.

- **Pn_HWSEL**
disable hardware selection; can be omitted if no hardware control is used on the port pin
- **Pn_PPS**
disable power save mode control of the pin; can be omitted if no power save configuration is used on the port pin
- **Pn_IOCRR**
tri-state input and no pull device active

18.8 Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 18-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|---|
| P0 | 4004 0000 _H | 4004 00FF _H | |
| P1 | 4004 0100 _H | 4004 01FF _H | High current bi-directional pad |
| P2 | 4004 0200 _H | 4004 02FF _H | Analog/Digital input and bi-directional pad |

18.8.1 Port Input/Output Control Registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up or pull-down devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-15). Each 32-bit wide port input/output control register controls four GPIO port lines:

Register Pn_IOCR0 controls the Pn.[3:0] port lines

Register Pn_IOCR4 controls the Pn.[7:4] port lines

Register Pn_IOCR8 controls the Pn.[11:8] port lines

Register Pn_IOCR12 controls the Pn.[15:12] port lines

The diagrams below show the register layouts of the port input/output control registers with the PCx bit fields. One PCx bit field controls exactly one port line Pn.x.

Pn_IOCR0 (n=0-1)

Port n Input/Output Control Register 0

(4004 0010_H + n*100_H)

1) Upon reset, the value of PC14 (P0.14) is 00000_B. The Startup Software (SSW) will change the PC14 value to input pull-up device active, 00010_B. Refer to the Startup chapter for more information.

General Purpose I/O Ports (Ports)

| Field | Bits | Type | Description |
|---|---|------|---|
| PC12, PC13, PC14, PC15 | [7:3], [15:11], [23:19], [31:27] | rw | Port Control for Port n Pin 12 to 15 This bit field determines the Port n line x functionality (x = 12-15) according to the coding table (see Table 18-5). |
| 0 | [2:0], [10:8], [18:16], [26:24] | r | Reserved Read as 0; should be written with 0. |

Depending on the GPIO port functionality (number of GPIO lines of a port), not all of the port input/output control registers are implemented.

The structure with one control bit field for each port pin located in different register bytes offers the possibility to configure the port pin functionality of a single pin with byte-oriented accesses without accessing the other PCx bit fields.

Port Control Coding

[Table 18-5](#) describes the coding of the PCx bit fields that determine the port line functionality.

The Pn_IOCRy PCx bit field is also used to control the pin behavior in Deep-Sleep mode if the Pin Power Save option is enabled, see [Chapter 18.8.7](#).

Table 18-5 Standard PCx Coding¹⁾

| PCx[4:0] | I/O | Output Characteristics | Selected Pull-up / Pull-down / Selected Output Function |
|--------------------|----------------|------------------------|---|
| 0X000 _B | Direct Input | — | No internal pull device active |
| 0X001 _B | | | Internal pull-down device active |
| 0X010 _B | | | Internal pull-up device active |
| 0X011 _B | | | No internal pull device active; Pn_OUTx continuously samples the input value |
| 0X100 _B | Inverted Input | — | No internal pull device active |
| 0X101 _B | | | Internal pull-down device active |
| 0X110 _B | | | Internal pull-up device active |
| 0X111 _B | | | No internal pull device active; Pn_OUTx continuously samples the input value |

General Purpose I/O Ports (Ports)
Table 18-5 Standard PCx Coding¹⁾ (cont'd)

| PCx[4:0] | I/O | Output Characteristics | Selected Pull-up / Pull-down / Selected Output Function |
|--------------------|-----------------------------|------------------------|---|
| 10000 _B | Output (Direct Input) | Push-pull | General-purpose output |
| 10001 _B | | | Alternate output function 1 |
| 10010 _B | | | Alternate output function 2 |
| 10011 _B | | | Alternate output function 3 |
| 10100 _B | | | Alternate output function 4 |

| 10110 _B | | | Alternate output function 6 |
| 10111 _B | | | Alternate output function 7 |
| 11000 _B | | Open-drain | General-purpose output |
| 11001 _B | | | Alternate output function 1 |
| 11010 _B | | | Alternate output function 2 |
| 11011 _B | | | Alternate output function 3 |
| 11100 _B | | | Alternate output function 4 |
| 11101 _B | | | Alternate output function 5 |
| 11110 _B | | | Alternate output function 6 |
| 11111 _B | | | Alternate output function 7 |

1) For the analog and digital input port P2.2 - P2.9, the combinations with PCx[4]=1_B is reserved.

18.8.2 Pad Hysteresis Control Register

The pad structure of the XMC1100 GPIO lines offers the possibility to select the pad hysteresis. These two parameters are controlled by the bit fields in the pad hysteresis control registers Pn_PHCR0/1, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCRR register. Pn_PHCR0 and Pn_PHCR1 registers are assigned to each port.

The 1-bit pad hysteresis selection bit field PHx in the pad hysteresis control registers Pn_PHCR make it possible to select the port line functionality as shown in [Table 18-6](#). Note that the pad hysteresis control registers are specific for each port.

Table 18-6 Pad Hysteresis Selection

| PHx | Functionality |
|-----|---------------------|
| 0 | Standard hysteresis |
| 1 | Large hysteresis |

General Purpose I/O Ports (Ports)

Note: Refer to Input/Output Characteristics table in the XMC1100 Data Sheet for hysteresis parameter values.

Pad Hysteresis Control Registers

This is the general description of the PHCR registers. Each port contains its own specific PHCR registers, described additionally at each port, that can contain between one and eight PHx fields for PHCR0 and PHCR1 registers, respectively. Each field controls 1 pin. For coding of PHx, see [Page 18-19](#).

18.8.3 Pin Function Decision Control Register

Pin Function Decision Control Register

The primary use for this register is to disable/enable the digital pad structure in shared analog and digital ports, see the dedicated description for [P2_PDISC](#).

For “normal” digital I/O ports (P0-P1) this register is read-only and the read value corresponds to the available pins in the given package.

18.8.4 Port Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn_IOC Rx as output. Writing a 0 to a Pn_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn_OUT.Px can be individually set/reset by writing appropriate values into the port output modification register Pn_OMR, avoiding read-modify-write operations on the Pn_OUT, which might affect other pins of the port.

The Pn_OUT is also used to store/drive a defined value for the input in Deep-Sleep mode. For details on this, see the [Port Pin Power Save Register](#). That is also the only use of the Pn_OUT register in the analog and digital input port P2.2 - P2.9.

18.8.7 Port Pin Power Save Register

When the XMC1100 enters Deep-Sleep mode, pins with enabled Pin Power Save option are set to a defined state and the input Schmitt-Trigger as well as the output driver stage are switched off.

Note: Do not enable the Pin Power Save function for pins configured for Hardware Control ($Pn_HWSEL.HWx \neq 00_B$). Doing so may result in an undefined behavior of the pin when the device enters the Deep Sleep state.

18.8.8 Port Pin Hardware Select Register

Some peripherals require direct hardware control of their I/Os. As multiple such peripheral I/Os are mapped on some pins, the register Pn_HWSEL is used to select which peripheral has the control over the pin.

Note: Pn_HWSEL.HWx just pre-assigns the hardware-control of the pin to a certain peripheral, but the peripheral itself decides when to take control over it. As long as the peripheral does not take control of a given pin via HWx_EN, the configuration of this pin is still defined by the configuration registers and it is available as GPIO or for other alternate functions. This might be because the selected peripheral has provisions to just activate a subset of its pins, or because the peripheral is not active at all.

This mechanism can also be used to prohibit the hardware control of certain pins to a peripheral, in case the application does not need the respective functionality and the peripheral has no provisions to disable the hardware control selectively.

| HWx (x = 0-11) | [2*x+1: 2*x] | rw | Port 2 Pin Hardware Select Bit x 00 _B Software control only. 01 _B HW0 control path can override the software configuration. 10 _B HW1 control path can override the software configuration. 11 _B Reserved. |
| 0 | [31:24] | r | Reserved Read as 0; should be written with 0. |

18.9 Package Pin Summary

The following general building block is used to describe each pin:

Table 18-9 Package Pin Mapping Description

| Function | Package A | Package B | ... | Pad Type |
|----------|-----------|-----------|-----|-----------|
| Px.y | N | N | | Pad Class |

The table is sorted by the “Function” column, starting with the regular Port pins (Px.y), followed by the supply pins.

The following columns, titled with the supported package variants, lists the package pin number to which the respective function is mapped in that package.

The “Pad Type” indicates the employed pad type:

- STD_INOUT (standard bi-directional pads)
- STD_INOUT/AN (standard bi-directional pads with analog input)
- High Current (high current bi-directional pads)
- STD_IN/AN (standard input pads with analog input)
- Power (power supply)

Details about the pad properties are defined in the Datasheet.

Table 18-10 Package Pin Mapping

| Function | VQFN 40 | TSSOP 38 | VQFN 24 | TSSOP 16 | Pad Type | Notes |
|----------|------------|-------------|------------|-------------|-----------|-------|
| P0.0 | 23 | 17 | 15 | 7 | STD_INOUT | |
| P0.1 | 24 | 18 | - | - | STD_INOUT | |
| P0.2 | 25 | 19 | - | - | STD_INOUT | |
| P0.3 | 26 | 20 | - | - | STD_INOUT | |
| P0.4 | 27 | 21 | - | - | STD_INOUT | |
| P0.5 | 28 | 22 | 16 | 8 | STD_INOUT | |
| P0.6 | 29 | 23 | 17 | 9 | STD_INOUT | |
| P0.7 | 30 | 24 | 18 | 10 | STD_INOUT | |
| P0.8 | 33 | 27 | 19 | 11 | STD_INOUT | |
| P0.9 | 34 | 28 | 20 | 12 | STD_INOUT | |
| P0.10 | 35 | 29 | - | - | STD_INOUT | |

| VDDP | 32 | 26 | - | - | Power | I/O port supply |
| VSSP | Exp. Pad | - | Exp. Pad | - | Power | Exposed Die Pad The exposed die pad is connected internally to VSSP. For proper operation, it is mandatory to connect the exposed pad to the board ground. For thermal aspects, please refer to the Package and Reliability chapter. |

18.10 Port I/O Functions

18.10.1 Port Pin for Boot Modes

Port functions can be overruled by the boot mode selected. The type of boot mode is selected via BMI. [Table 18-11](#) shows the port pins used for the various boot modes.

Table 18-11 Port Pin for Boot Modes

| Pin | Boot | Boot Description |
|------------|-------------|--------------------------|
| P0.13 | CS(O) | SSC BSL mode |
| P0.14 | SWDIO_0 | Debug mode (SWD) |
| | SPD_0 | Debug mode (SPD) |
| | RX/TX | ASC BSL half-duplex mode |
| | RX | ASC BSL full-duplex mode |
| | SCLK(O) | SSC BSL mode |
| P0.15 | SWDCLK_0 | Debug mode (SWD) |
| | TX | ASC BSL full-duplex mode |
| | DATA(I/O) | SSC BSL mode |
| P1.2 | SWDCLK_1 | Debug mode (SWD) |
| | TX | ASC BSL full-duplex mode |
| P1.3 | SWDIO_1 | Debug mode (SWD) |
| | SPD_1 | Debug mode (SPD) |
| | RX/TX | ASC BSL half-duplex mode |
| | RX | ASC BSL full-duplex mode |

18.10.2 Port I/O Function Description

The following general building block is used to describe the I/O functions of each PORT pin:

Table 18-12 Port I/O Function Description

| Function | Outputs | | Inputs | |
|----------|----------|----------|----------|----------|
| | ALT1 | ALTn | Input | Input |
| P0.0 | | MODA.OUT | MODC.INA | |
| Pn.y | MODA.OUT | | MODA.INA | MODC.INB |

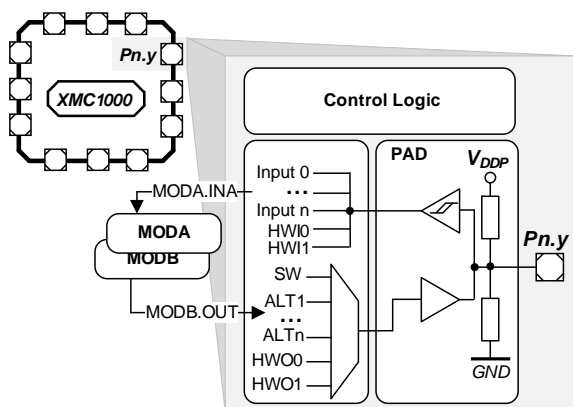

Figure 18-4 Simplified Port Structure

Pn.y is the port pin name, defining the control and data bits/registers associated with it. As GPIO, the port is under software control. Its input value is read via Pn_IN.y, Pn_OUT defines the output value.

Up to seven alternate output functions (ALT1/2/3/4/5/6/7) can be mapped to a single port pin, selected by Pn_IOC.R.PC. The output value is directly driven by the respective module, with the pin characteristics controlled by the port registers (within the limits of the connected pad).

The port pin input can be connected to multiple peripherals. Most peripherals have an input multiplexer to select between different possible input sources.

The input path is also active while the pin is configured as output. This allows to feedback an output to on-chip resources without wasting an additional external pin.

Please refer to the [Port I/O Functions](#) table for the complete Port I/O function mapping.

18.10.3 Hardware Controlled I/O Function Description

The following general building block is used to describe the hardware I/O and pull control functions of each PORT pin:

Table 18-13 Hardware Controlled I/O Function Description

| Function | Outputs | Inputs | Pull Control | |
|----------|----------|----------|--------------|----------|
| | HWO0 | HWI0 | HW0_PD | HW0_PU |
| P0.0 | MODB.OUT | MODB.INA | | |
| Pn.y | | | MODC.OUT | MODC.OUT |

By Pn_HWSEL ([Chapter 18.8.8](#)) it is possible to select between different hardware “masters” (HWO0/HWI0, HWO1/HWI1). The selected peripheral can take control of the pin(s). Hardware control overrules settings in the respective port pin registers. Additional hardware signals HW0_PD/HW1_PD and HW0_PU/HW1_PU controlled by the peripherals can be used to control the pull devices of the pin.

Please refer to the [Hardware Controlled I/O Functions](#) table for the complete hardware I/O and pull control function mapping.

Table 18-14 Port I/O Functions

| Function | Outputs | | | | | | | Inputs | | | | | | |

Boot and Startup, Bootstrap Loaders, and User Routines

19 Boot and Startup

The startup sequence of the XMC1100 is a process taking place before user application software takes control of the system and is comprising of two major phases (see [Figure 19-1](#)), split in several distinctive steps:

Hardware Controlled Startup Phase

The hardware controlled startup phase gets performed automatically after power up of the microcontroller. This part is generic and it ensures basic configuration common to most applications. The hardware setup needs to ensure fulfillment of requirements specified in Data Sheet in order to enable reliable start up of the microcontroller before control is handed over to the user software. The sequence where boot code gets executed is considered a part of the hardware controlled phase of the startup sequence.

For details of the setup requirements, please refer to Data Sheet.

Software Controlled Startup Phase

The software controlled startup phase is the part where the application specific configuration gets applied with user software. It involves several steps that are critical for proper operation of the microcontroller in the application context and may also involve some optional configuration actions in order to improve system performance and stability in the application context.

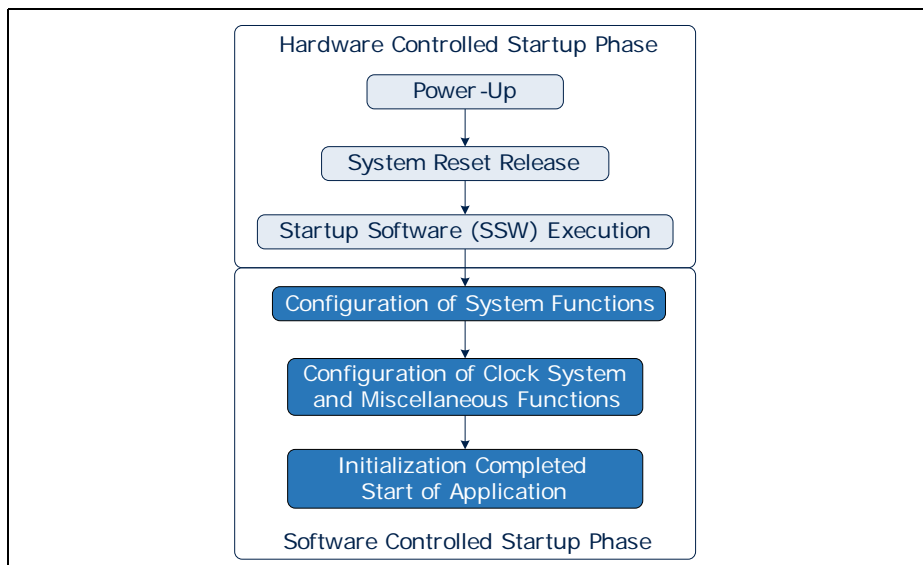

Figure 19-1 Startup sequence

19.1 Startup Sequence and System Dependencies

A more detailed description of the startup sequence is available in the following sub-chapters.

19.1.1 Power-Up

Power up of the microcontroller gets performed by applying V_{DDP} supply (for details of the supply requirements, please refer to Data Sheet). Once V_{DDP} reaches a threshold, the internal core voltage, V_{DDC} , is generated automatically by the EVR.

19.1.2 System Reset Release

The internal power-on reset generation is based on the supply and core voltage validation. When V_{DDP} and V_{DDC} reaches a stable threshold level, the power-on reset is released. Next, after the on-chip oscillators generate a stable clock output, the system reset is released automatically and the SSW code starts to run.

The system reset can be triggered from various sources like software controlled CPU reset register or a watchdog time-out-triggered reset. For more details on reset control details, please refer to the Reset Control Unit (RCU) section in the SCU chapter.

The cause of the last reset gets automatically stored in the SCU_RSTSTAT register and can be checked by user software to determine the state of the system and for debug purpose. The reset status in the SCU_RSTSTAT register shall be reset with SCU_RSTCLR register after each startup in order to ensure consistent source indication after the next reset.

After reset release, MCLK and PCLK are running at 8MHz and most of the peripherals' clocks are disabled except for CPU, memories and PORT. It is recommended to disable the clock of the unused modules in order to reduce power consumption.

19.1.3 Startup Software (SSW) Execution

After the reset is deasserted, CPU starts to execute the SSW code from the ROM memory. To indicate the start of the SSW execution, the pullup device in P0.14 is enabled. Pullup device is disabled during reset.

Another important task that is done by SSW is to read the Boot Mode Index (BMI) stored in Flash and decide the startup mode (such as User Productive mode and Bootstrap Loader) selected by the user. For more details about the various startup modes and handling of BMI, please refer to [Section 19.2](#).

To handle the initial hardfault error during the SSW execution, SSW installs "jump to itself" instruction at SRAM location $2000'000C_H$ as temporary HardFault handler - until the user code installs its own. It is installed upon master reset only.

During SSW execution, the SRAM area between 2000'00C0_H and 2000'0200_H is reserved for usage by XMC1100 SSW, therefore the user software should not store in this area data which must be preserved throughout (non-power) resets.

The MCLK and PCLK frequency that is used to execute the SSW and to start the user code can be configured by user. In addition, some of the peripheral clock can also be enabled (default disabled) by the SSW. Detailed description can be found in the

Section 19.1.3.1.

19.1.3.1 Clock system handling by SSW

XMC1100 SSW is able to change device clock settings to allow flexibility of device performance e.g. speed vs. power consumption optimization during start-up.

The clock handling by SSW is user configurable by installing values in Flash. For this purpose two word locations - CLK_VAL1 and CLK_VAL2 - are assigned in Flash (refer to [Table 19-1](#)), the values from these locations are processed by SSW as follows:

- if CLK_VAL1[31]=0 - CLK_VAL1[19:0] bits are installed into SCU_CLKCR[19:0] register - this configures clock dividers and selection
- if CLK_VAL2[31]=0 - CLK_VAL2[10:0] bits are installed into SCU_CGATCLR0[10:0] - this enables the clock of the selected peripherals

In case some CLK_VALx location is not programmed by the user - like in device delivery state - its bit[31]=1 and no installation is done into the respective register(s).

Limited device frequency change

To avoid big jumps/drops in power consumption, the user-configurable value to be installed during start-up from CLK_VAL1 into CLKCR.IDIV is limited to the range 1..16, resulting in possible range of MCLK after re-configuration 2..32 MHz from initial 8MHz - i.e. MCLK frequency can be increased or decreased no more than 4 times (rounded, ignoring potential FDIV influence).

In case CLK_VAL1 (refer to [Table 19-1](#)) contains IDIV value out of the 1..16 range:

- if IDIV=0 - SSW installs IDIV=1 instead
- if IDIV>16 - SSW install IDIV=16 instead

19.1.4 Configuration of Special System Functions as part of User code initialization

Special system functions may be required to perform actions that improve system stability and robustness. The following special system functions or modules require initialization as part of the User code initialization before the actual user application starts:

- Start Address and Initial Stack Pointer Value
- Setup the Interrupt handler

- Supply Voltage Brown-out Detection
- Watchdog Timer (WDT)

Start Address and Initial Stack Pointer Value

The start address and the initial stack pointer values in [Table 19-1](#) need to be defined by the user. It can be done together with the downloading of the user code into the flash memory.

Setup the Interrupt Handler

The vector table is remapped to the SRAM based on the remapped vector table in CPU chapter. The interrupt service routine can be placed in these SRAM address or user can also have a branch instruction to the routine that is placed in other memory location. For details, please refer to CPU chapter.

V_{DDP} Brown Out Detection

V_{DDP} brown out detection mechanism allows active monitoring of the supply voltage and a corrective reaction in case the voltage level is below a programmed threshold. An interrupt request will be flagged if a programmed condition is detected. For details, please refer to the Power Control Unit (PCU) section in the SCU chapter.

Watchdog Timer

The Watchdog Timer requires a clock source selection and activation. It is highly recommended to use a reliable clock source, preferably independent from the system clock source in order to ensure corrective action in case of a system failure which will bring the microcontroller into a safe operation state. In XMC1100, the default WDT clock is the standby clock. For more details, please refer to WDT chapter. For details of the WDT module configuration, please refer to the “Initialization and Control Sequence” section of the WDT chapter.

19.1.5 Configuration of Clock System and Miscellaneous Functions

The following functions are available and may require configuration in the user code:

- Clock System Configuration
- System Reset Configuration
- Debug Suspend Configuration

Clock System Configuration

MCLK and PCLK frequency can be configured to be different from the user settings during SSW execution as described in [Section 19.1.3.1](#). The SCU_CRCLK.IDIV/FDIV bits are used to program the target clock frequency. The ratio between MCLK and PCLK is also selectable via bit SCU_CRCLK.PCLKSEL. In addition, some of the peripheral

clocks can be enable/disable via the SCU_CGATCLR0/SCU_CGATSET0 register respectively. It is also recommended to enable the oscillator watchdog for loss of clock detection.

System Reset Configuration

Several events such as Flash ECC error or SRAM parity error can be used to trigger a system reset using the SCU_RSTCON register. For details, please refer to the reset control unit (RCU) section in the SCU chapter.

Debug Suspend Configuration

The XMC1100 device supports a suspend capability for peripherals, if the program execution of the CPU is stopped by the debugger, e.g. with a breakpoint, or with the C_HALT. This allows the debugging of critical states of the whole microcontroller. The suspend function has to be enabled or disabled locally at the peripheral based on the application and the debugging approach. Refer to Debug System chapter for details.

19.2 Start-up Modes

Startup Software (short name SSW) is the first software executed by CPU after any device leaves reset state.

SSW is stored in the ROM memory, but nevertheless its flow is influenced by other “flexible” factors as:

- type of the event triggering SSW execution
- start-up configuration as selected by the user in so called Boot Mode Index (short notation BMI)

19.2.1 Start-up modes in XMC1100

Start-up mode selection in XMC1100 is done by the SSW after reset. It is based on **Boot Mode Index (BMI)** stored in flash configuration sector 0 (CS0) meaning no device pin is used for configuration purpose. To program a new BMI, user need to call the user function “Request BMI installation” as described in the BSL and User Routines chapter. The selection and handling of BMI by SSW is described in **Section 19.2.3**. The default start-up mode in device delivery state is the ASC BSL mode.

A summary of the supported start-up modes follows.

19.2.1.1 User productive mode

User code is started from Flash memory, no debugging is possible in this mode.

The address of the first user instruction - to where SSW jumps at its end - is taken from Flash location 1000'1004_H.

SSW does not check either the target address is inside user Flash. Therefore HardFault will be generated if it's outside and the execution will jump to exception handler in SRAM (upon master reset an endless loop is installed by SSW).

19.2.1.2 User mode with debug enabled

User code is started from Flash memory, the first address is determined as in [User productive mode](#) (see [Section 19.2.1.1](#)).

Debug interface is configured according to [Boot Mode Index \(BMI\)](#) value and enabled.

19.2.1.3 User mode with debug enabled and Halt After Reset (HAR)

User code is started from Flash memory as in the two modes above.

Debug interface is configured according to BMI value and enabled, the CPU is stalled upon exit from SSW and before the first user instruction (for the handling refer to [Section 19.2.3.2](#)).

19.2.1.4 Standard Bootstrap Loader modes

In this mode (short notation Standard BSL):

- user code is downloaded into SRAM
- at the SSW end the execution jumps to SRAM
- no debugging is possible

The Standard BSL mode supported in XMC1100 uses USIC0 module for communication with the host:

- ASC - using channel 0 or 1 (auto-detection by firmware) of USIC0 module and ASC (UART) protocol for download
This is the default start-up mode - selected by BMI value in device delivery state.
- SSC - using USIC0 channel 0 and SSC (SPI) standard protocol for download
In this mode SPI-compatible serial EEPROM is supposed to be connected as slave device to XMC1100.

The functionality of standard BSL routines is described in the BSL chapter.

19.2.1.5 Bootstrap Loader modes with time-out

These modes are using the Standard BSL routines for downloading, but the functionality is different:

- SSW first checks either an external device is connected/active, meaning SSW waits to receive Start and Header Bytes from the host - either via USIC channel 0 or 1 - for time-out which duration is taken from BMI.BLSTO (refer to [Section 19.2.2](#)):

- if yes
 - * user code is downloaded into SRAM
 - * at the SSW end the execution jumps to SRAM
- if not - at the SSW end the execution jumps to Flash as in **User productive mode**
- no debugging is possible in this mode, independently either code execution starts from Flash or SRAM

Two BSL modes with time-out are supported in XMC1100, both using USIC0 module for communication with the host. Besides the difference in interface selection, also the check performed as part from the above sequence is different:

- ASC mode
 - SSW configures USIC0 channels 0 and 1 in ASC (UART) mode
 - SSW waits to receive Start and Header Bytes from the host - either via channel 0 or 1 - for time-out which duration is taken from BMI.BLSTO (refer to **Section 19.2.2**)
 - if Start+Header Bytes are received - Standard ASC BSL is further executed for downloading and starting user code from SRAM; otherwise execution from Flash will be taken
- SSC mode
 - SSW configures USIC0 channel 0 as Master in SSC (SPI) mode
 - SSW initiates communication with SPI-compatible serial EEPROM supposed to be connected as slave device
 - if data received upon Read Command sent by SSW corresponds to the expected (serial EEPROM) protocol - Standard SSC BSL is further executed for downloading and starting user code from SRAM; otherwise execution from Flash will be taken

Note: If BSLTO=0 is configured in BMI - SSW at all does not perform any BSL check but directly takes User Productive Mode.

19.2.2 Boot Mode Index (BMI)

The Boot Mode Index is 2 Byte value stored in Flash (refer to [Table 19-1](#)) and holding information about start-up mode and debug configuration of the device. Additionally to BMI at 1000'0E00_H its inverse value is stored at 1000'0E10_H for check purposes.

BMI

| Boot Mode Index | | | | CS0 offset 0E00 _H | | | | Delivery state: FFC0 _H | | | | | | | |
|-----------------|----|----|----|------------------------------|-------|---|------------|-----------------------------------|--------|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| BSLTO | | | | 1 | DAPIS | | DAP TYP | 1 | HWCFCG | | | | | | |
| r | | | | r | r | | r | r | r | | | | | | |

| Field | Bits | Typ | Description |
|--------|--------------|-----|--|
| HWCFCG | [5:0] | r | Start-up mode selection: 000000 _B ASC Bootstrap Loader mode (ASC_BSL) 000001 _B User productive Mode (UPM) 000011 _B User mode with debug enabled (UMD) 000111 _B User mode with debug enabled and HAR (UMHAR) 001000 _B SSC Bootstrap Loader mode (SSC_BSL) 010000 _B ASC BSL mode with time-out (ASC_BSLTO) 011000 _B SSC BSL mode with time-out (SSC_BSLTO) 101010 _B Secure Bootstrap Loader mode (SBSL) ¹⁾ else Not defined ²⁾ |
| DAPTYP | 8 | r | DAP Type Selection Coding as of SCU_DAPCON.DAPTYP |
| DAPDIS | [10:9] | r | SWD/SPD Input/Output Selection Coding as of SCU_DAPCON.DAPDIS |
| BSLTO | [15:12] | r | ASC BSL Time-out value The time-out duration is BSLTO*2664000 MCLK cycles, the supported time-out range is 0.3-5s (333...4995ms) |
| 1 | [7:6], 11 | r | Reserved, must be programmed to 1 |

1) Only in device versions supporting it

2) ATTENTION: Installing one of these values will cause device delivery state to be restored upon the next reset - refer to [Section 19.2.3](#)

19.2.3 Start-up mode selection

The start-up modes in XMC1100 are selected and handled according to Boot Mode Index (BMI) value read from Flash - refer to [Section 19.2.1](#).

The BMI evaluation can lead to:

- taking User mode - SSW will jump at its end into User Flash and start execution from the location which address is stored at 1000'1004_H if:
 - a kind of User Mode is selected in BMI
 - ASC BSL with time-out is selected but no valid Start+Header Bytes are received within the selected time frame
- taking Bootstrap Loader mode - executing ASC BSL then jumping into SRAM at 2000'0200_H
- taking Secure Bootstrap Loader (SBSL) mode - if SBSL is selected in BMI and supported for the device
- executing (endless) loop - waiting for valid Start+Header Bytes to be received via ASC upon ASC BSL mode selected without time-out
- erasing the complete user Flash and installing ASC BSL (or SBSL if supported) mode as new BMI value - upon invalid BMI value or if Secure BSL is selected but not supported for the device. Afterwards master reset is triggered and device is started in a mode according to the new BMI.

19.2.3.1 BMI handling by SSW

This SSW part is intended to be executed after the user function (in ROM) "Request BMI installation" (described in the BSL and User Routines chapter) has been called and has triggered a system reset. Therefore the conditions under which this handling is performed are:

- the last reset was a system reset requested by CPU
- the two half words of SSW0 register are inverse to each other

If all the above conditions are true, the SSW considers SSW0[15:0] content as new BMI value to be installed and executes the following:

- check either the current BMI (in CS0) is User_Productive AND the new value is NOT User_Productive:
 - if yes - erase the complete user Flash and install ASC_BSL (or SBSL if supported) mode as new BMI value
 - if not - install the new BMI value from SSW0[15:0]
- instal all zero in SSW0 to indicate no BMI-programming upon the next reset
- request master reset to be triggered

Upon the last action, a master reset is triggered and a next SSW execution will start with the new BMI value installed in CS0.

19.2.3.2 Debug system handling

If debug system must be enabled - start-up mode with debug support is selected in Boot Mode Index (refer to [Section 19.2.2](#)) - SSW performs the following:

- configure the debug interface from BMI value
- enable the debug interface
- if start-up mode with Halt After Reset request (UMHAR) is selected in BMI upon master reset - enter an endless NOP (no operation) loop. From this point on, an external tool (debugger) can take over the control of the device, in particular:
 - if/when a debugger connects to device, it can halt the CPU and check BMI and/or the core program counter (PC) register
 - if HAR is selected, this can be identified by BMI value (refer to [Section 19.2.2](#)) and the PC value will point inside the ROM. The debugger can then manipulate PC and start the user code as desired - the default start address (taken without HAR) is according to the content at location 1000'1004_H in user Flash (refer to [Table 19-1](#))

19.3 Data in Flash for SSW and User SW

[Table 19-1](#) shows the data in Flash which is relevant for SSW execution and can be used by user software in XMC1100.

Table 19-1 Flash data for SSW and user SW in XMC1100

| Address | Length | Function | Target location |
|--|--------|------------------------------------|-----------------|
| Start-up mode selection: | | | |
| 1000'0E00 _H | 2 B | Boot Mode Index (BMI) | --- |
| 1000'0E10 _H | 2 B | Inverse BMI | --- |
| Chip Identification: | | | |
| 1000'0F00 _H | 4 B | Chip ID | SCU_IDCHIP |

20 Bootstrap Loaders (BSL) and User Routines

This chapter describes the Bootstrap Loaders (BSL) and the user-accessible routines in the ROM memory.

The ASC (UART) BSL ([Section 20.1](#)) and the SSC BSL ([Section 20.2](#)) is entered with the BMI settings as described in the Boot and Startup Chapter. The main purpose of BSL Mode is to allow easy and quick programming/erasing of the Flash.

[Section 20.3](#) describes 5 user-accessible routines that can be called by application software. These routines are located in the ROM memory.

20.1 ASC (UART) Bootstrap Loader

ASC (UART) Standard Bootstrap Loader (ASC BSL) in XMC1100 uses USIC0 module to download code/data into SRAM starting at address 2000'0200H.

After the last code/data Byte is received and stored, the Startup Software starts user code from address 20000'0200H.

20.1.1 Pin usage

ASC BSL in XMC1100 is selected by a single BMI value but it allows to download user code/data via several variants of pins, modes and USIC0 channels:

- Channel 0
 - full duplex mode with RxD at P0.14 and TxD at P0.15
 - half duplex mode with RxD/TxD at P0.14
- Channel 1
 - full duplex mode with RxD at P1.3 and TxD at P1.2
 - half duplex mode with RxD/TxD at P1.3

Note: The above set of pins also accommodate all the assignments for SWD/SPD (debug) interfaces.

20.1.2 ASC BSL execution flow

The complete ASC Bootstrap Loader procedure consists of two parts as described below.

20.1.2.1 ASC BSL entry check sequence

Downloading is only initiated after a Start (zero) and a Header (described below) Bytes are received through one of the channels whereas both the channels are active ("listening") until the selection is done by the routine itself as follows:

- Channel selection - based on the fact at which RxD pin (see the above assignments) first Start+Header Bytes are received
- Full/half duplex selection - based on the Header Byte received

Bootstrap Loaders (BSL) and User Routines

*Note: For definitions of header/acknowledge byte values exchanged with the host - refer to **Section 20.1.3**.*

The ASC bootloader functionality includes:

1. enable and configure the both USIC0 communication channels 0 and 1 as follows:
 - a) ASC mode, 8 data bits, 1 stop bit, no parity
2. configure ASC clock-generation circuitry for measurement
3. perform continuously the following sequence for both USIC0 channels one after another
 - a) check either Start zero Byte has been received
if yes - then:
 - b) reconfigure ASC clock-generating circuitry for normal operation according to the baudrate measured from the Start Byte, then:
 - c) check either Header Byte has been received
if yes - then:
 - d) check the Header Byte received
 - * if equal to BSL_ASC_F or BSL_ENC_F - full duplex mode is selected - continue with step 4.
 - * if equal to BSL_ASC_H or BSL_ENC_H - half duplex mode is selected - continue with step 4.
 - * otherwise - go to sequence for the other channel
4. select the current (Cy) channel for further handling; restore default configuration for the channel C(y-1) which is not selected
5. for the selected channel and mode (full/half duplex) :
 - a) configure TxD pin and ASC transmitter
 - b) adapt (in case) RxD pin settings
 - c) enable transmission, single shot mode
6. check which Header byte was received:
 - a) BSL_ASC_F or BSL_ASC_H - standard BSL entry sequence was executed, the communication will use further the baudrate detected - continue with **ASC BSL download sequence** (see **Section 20.1.2.2**)
 - b) BSL_ENC_F or BSL_ENC_H - the communication during **ASC BSL download sequence** will potentially use different (e.g. higher) baudrate than the initially detected - continue with the **Enhanced ASC BSL entry sequence** (see below))

The above check sequence is executed

- in ASC BSL mode without time-out - until valid Start+Header Bytes are received
- otherwise - only for some time according to BMI.BSLTO

Note: If mode with time-out is selected but BMI.BSLTO=0 - User mode with start from Flash is directly taken.

Bootstrap Loaders (BSL) and User Routines

Enhanced ASC BSL entry sequence

This is an extension of the standard [ASC BSL entry check sequence](#) and will be used when higher baudrates are required for the communication channel.

It includes the following steps:

1. Send BSL_ENC_ID to acknowledge the establishment of the initial baud rate and entry into enhanced ASC BSL
2. Send current PDIV divider from USIC0_CHy_BRG register - the 10-bit value is sent in 2 bytes (most significant byte first)
3. Receive from host the 10-bit value to be written into the STEP bit field in USIC0_CHy_FDR register
4. Send BSL_BR_OK to acknowledge the establishment of the new baud rate
5. Configure USIC baud rate generator accordingly
6. Receive from host BSL_BR_OK to indicate that the communication channel has been successfully established
 - If no or wrong acknowledge value is received, a device software reset will be triggered

[Figure 20-1](#) shows the outline of the sequence to configure the baud rate.

Requirements for Host

For the host to support enhanced ASC BSL, the host additionally has to:

- Receive from XMC1100 device, the current 10-bit PDIV value in USIC0_CHy_BRG register
- Calculate the MCLK that the device is running on based on the received PDIV through the formula:

(20.1)

$$\text{MCLK} = \text{Initial Baud Rate} \times (\text{PDIV} + 1) \times 8$$

- Select a new baud rate that is supported by the enhanced ASC BSL given the MCLK (see [Table 20-1](#))
- Calculate the scaling factor, i.e. ratio of the new baud rate to the initial baud rate. Some examples are given in [Table 20-2](#). The scaling factor is rounded to the nearest integer in order to meet a frequency deviation of +/- 3%.

Bootstrap Loaders (BSL) and User Routines

Table 20-1 Supported Baud Rates

| MCLK (MHz) | Standard baud rates supported with ASC BSL (kHz) | | Max. baud rate supported with Enhanced ASC BSL (MHz) |
|------------|--|-------|--|
| | Min. | Max. | |
| 8 | 1.2 | 28.8 | 0.999 |
| 16 | 2.4 | 57.6 | 1.998 |
| 32 | 4.8 | 115.2 | 3.996 |

Table 20-2 Scaling Factor Examples

| Initial standard baud rates (kHz) ---A | Targeted higher baud rates (kHz) ---B | Scaling factor rounded to the nearest integer (B/A) |
|--|---------------------------------------|---|
| 9.6 | 1500 | 156 |
| 19.2 | 1500 | 78 |
| 57.6 | 1500 | 26 |
| 115.2 | 1500 | 13 |

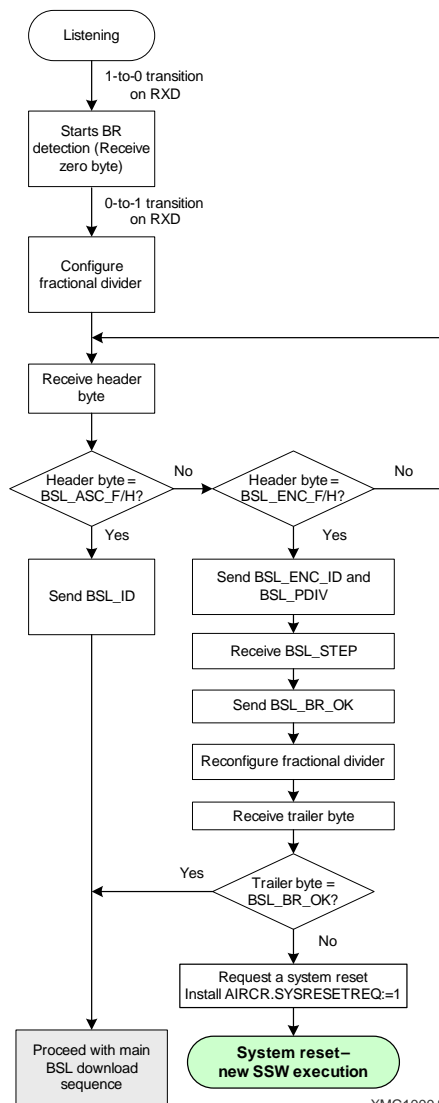

- Calculate the 10-bit value to be written into the STEP bit field of USIC0_CHy_FDR register through the formula:

(20.2)

$$\text{STEP (in fractional divider mode)} = \frac{1024 \times \text{Scaling Factor}}{\text{PDIV} + 1}$$

- Send the 10-bit STEP value to the device
- Wait until the BSL_BR_OK is received from the device
- Echo the BSL_BR_OK back to the device

Bootstrap Loaders (BSL) and User Routines

XMC1000 SBSL BR detection flow

Figure 20-1 Baud Rate configuration sequence during XMC1100 ASC BSL entry

Bootstrap Loaders (BSL) and User Routines

20.1.2.2 ASC BSL download sequence

After the baud rate has been detected/configured and channel/mode (full/half duplex) selected, ASC BSL awaits 4 bytes describing the length of the application from the host (refer to [Figure 20-2](#)). The least significant byte is received first.

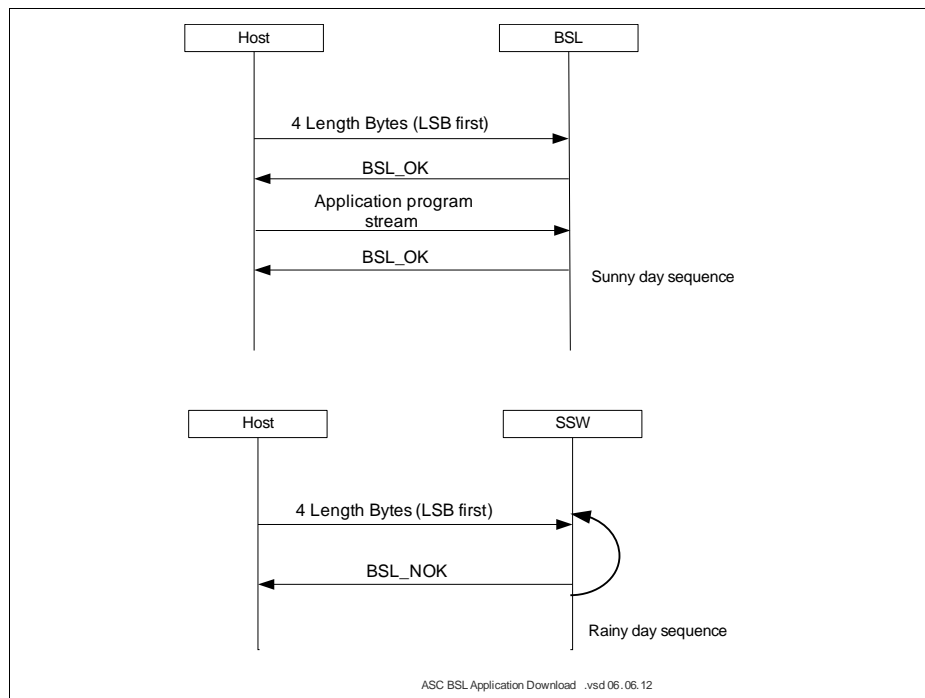

Figure 20-2 XMC1100 Standard ASC BSL: Application download protocol

If application length is found alright by SSW, a BSL_OK byte is sent to the host following which the latter sends the byte stream belonging to the application. After the byte stream has been received, SSW terminates the protocol by sending a final OK byte and then cedes control to the downloaded application.

If application length is found to be in error (application length greater than device SRAM size), a BSL_NOK byte is transmitted back to the host and the SSW resumes awaiting the length bytes.

Bootstrap Loaders (BSL) and User Routines

20.1.3 ASC BSL protocol data definitions

The interaction between XMC1100 ASC Bootstrap Loader routine and the host implements handshake protocol based on [Figure 20-3](#) and request/acknowledge/data Bytes defined in [Table 20-3](#).

Table 20-3 Handshake protocol data definitions in XMC1100 ASC BSL

| Name | Length, Byte | Value | Description |
|---|--------------|-------------------|--|
| Requests/data/acknowledge sent by the Host: | | | |
| BSL_ASC_F | 1 | 6CH | Header requesting full duplex ASC mode with the current baud rate |
| BSL_ASC_H | 1 | 12H | Header requesting half duplex ASC mode with the current baud rate |
| BSL_ENC_F | 1 | 93 _H | Header requesting full duplex ASC mode with a request to switch the baud rate |
| BSL_ENC_H | 1 | ED _H | Header requesting half duplex ASC mode with a request to switch the baud rate |
| BSL_STEP | 2 | 0XXX _H | 10-bit value (LSB aligned) to be programmed into selected USIC channel's FDR.STEP bit field. Most significant 6 bits should contain all 0. |
| BSL_BR_OK | 1 | F0 _H | Final baud rate is established in enhanced ASC BSL |
| Acknowledges sent by XMC1100 firmware: | | | |
| BSL_ID | 1 | 5DH | Start and header bytes are received, baud rate is established |
| BSL_ENC_ID | 1 | A2 _H | Start and header byte(s) are received in enhanced ASC BSL, initial baud rate is established |
| BSL_PDIV | 2 | 0XXX _H | 10-bit value (LSB aligned) containing the selected USIC channel's BRG.PDIV bit field value. Most significant 6 bits should contain all 0. |
| BSL_BR_OK | 1 | F0 _H | Final baud rate is established in enhanced ASC BSL. |
| BSL_OK | 1 | 01H | Data received is OK |
| BSL_NOK | 1 | 02H | Failure encountered during data reception |

Bootstrap Loaders (BSL) and User Routines

Figure 20-3 Handshake protocol for XMC1100 ASC BSL entry

Bootstrap Loaders (BSL) and User Routines

20.2 SSC Bootstrap loader

This procedure downloads code from a SPI-compatible serial EEPROM into SRAM starting at address 2000'0200H using Channel 0 of USIC0 Module. The length of the code can be arbitrary up to the user-available SRAM size.

XMC1100 is the master SPI-device, following pins are used by the bootloader:

- MRST (master data input) and MTSR (master data output) - on the same P0.15, half-duplex mode used
- SCLK (clock signal) - P0.14, open drain
- SLS (chip-select CS to the EEPROM) - P0.13, open drain

Note: Due to the specific functionality of the bootloader - performing one Sequential Read operation only - there is no need of a dedicated SLS-control.

Note: Due to XMC1100 pin configured as open drain, external pull-up resistors need to be added on the bus

A SPI-compatible serial EEPROM of type 25xxx must be connected to the pins as above defined. The clock signal is configured at MCLK/10 frequency upon device startup.

The SSC bootloader in XMC1100 is able to communicate with a very broad range on serial-EEPROM types: from such using 8-bit addressing (size up to 2K bit, quite outdated already) up to devices using 24-bit addressing (1M bit and above). The connected EEPROM type is determined by examining the received header bytes, as indicated in

Table 20-4.

Note: Besides the bootloader supports all the device-types, the code/data length which can be downloaded is limited by the size of available SRAM.

Table 20-4 SSC BL: Determining the EEPROM Type and data-flow

| SSC Frame | | EEPROM with 8-bit addressing connected | | EEPROM with 16-bit addressing connected | | EEPROM with 24-bit addressing connected | |
|-----------|-----------------|--|-------------------------------|---|-------------------------------|---|-------------------------------|
| N | data | P11-send | P11-receive | P11-send | P11-receive | P11-send | P11-receive |
| 1 | 03 _H | Read command | XX _H default level | Read command | XX _H default level | Read command | XX _H default level |
| 2 | 00 _H | Address | XX _H | Address_H | XX _H | Address_H | XX _H |
| 3 | 00 _H | dummy | Identification | Address_L | XX _H | Address_M | XX _H |

Bootstrap Loaders (BSL) and User Routines
Table 20-4 SSC BL: Determining the EEPROM Type and data-flow

| SSC Frame | | EEPROM with 8-bit addressing connected | | EEPROM with 16-bit addressing connected | | EEPROM with 24-bit addressing connected | |
|-----------|-----------------|--|-------------|---|----------------|---|-----------------|
| 4 | 00 _H | dummy | Size | dummy | Identification | Address_L | XX _H |
| 5 | 00 _H | dummy | Data Byte 1 | dummy | Size, High B | dummy | Identification |
| 6 | 00 _H | dummy | Data Byte 2 | dummy | Size, Low B | dummy | Size, High B |
| 7 | 00 _H | dummy | Data Byte 3 | dummy | Data Byte 1 | dummy | Size, Mid B |
| 8 | 00 _H | dummy | Data Byte 4 | dummy | Data Byte 2 | dummy | Size, Low B |
| 9 | ... | dummy | Data Byte 5 | dummy | Data Byte 3 | dummy | Data Byte 1 |
| ... | | | ...n | | ...n | | ...n |

The EEPROM connected for downloading must contain:

- identification Byte D5H at the first address (0000H)
- the length of the code (Code_Length) in Bytes as follows:
 - in case of an EEPROM with 8-bit addressing - in one Byte at address 0001H
 - in case of an EEPROM with 16-bit addressing - in two Bytes at addresses 0001H/0002H ordered high/low
 - in case of an EEPROM with 24-bit addressing - in three Bytes at addresses 0001H/0002H/0003H ordered high/middle/low
- the code of defined length follows sequentially

The SSC bootloader functionality includes:

1. enable the communication channel by setting USIC0_C0_KSCFG.MODEN:=1
2. assure clock gating for USIC0 module is de-asserted
3. configure the USIC0_C0 channel as follows:
 - a) SSC mode, 8 data bits, MSB first
 - b) SCLK frequency = MCLK/10
 - c) no SLS activated
 - d) pin-configuration as defined above
 - e) enable transmission
4. de-select EEPROM by setting CS=1
5. enable EEPROM (CS=0) and send Read command (03h)
6. send two zero Bytes to request data from address 0000h
7. Upon any next Byte transfer as long as the EEPROM is still selected (CS=0) - data from then next following address will be read out.
8. the last Byte received is checked:

Bootstrap Loaders (BSL) and User Routines

- a) if equal to the Identification Byte (D5H) - the EEPROM uses 8-bit addressing:
 - SSW reads one more Byte and saves it as Code_Length - 1B only effective
 - continue with p.10
- 9. read one more Byte:
 - a) if equal to the Identification Byte (D5H) - the EEPROM uses 16-bit addressing:
 - SSW reads two Bytes in order High/Low to determine Code_length (2 Bytes)
 - continue with p.10
- 10. read one more Byte:
 - a) if equal to the Identification Byte (D5H) - the EEPROM uses 24-bit addressing:
 - SSW reads three more Bytes in order High/Middle/Low to determine Code_length (3 Bytes)
 - continue with p.10
 - b) if Not - directly exit the sequence
- 11. check the value of Code_length:
 - a) if 0 or greater than allowed in XMC1100- directly exit the sequence
- 12. read [Code_Length] Bytes and store them sequentially from the beginning of SRAM (address 2000'0200H) on
- 13. disable EEPROM (CS=1)
- 14. disable the communication channel by resetting USIC0_C0_KSCFG.MODEN:=0
- 15. set SSW flag BSL_act=1 and exit the sequence

After the last Byte is received and stored, the Startup Software starts the code downloaded from address 20000'0200H.

20.3 Firmware routines available for the user

Several user routines (refer to [Table 20-5](#)) are available inside ROM so they can be called by application software.

Table 20-5 User routines' in XMC1100 ROM

| XMC1100 ROM | | Description |
|--------------------|---------------------|---|
| Address | Content | |
| 0000'0100H | _NvmErase | Pointer to Erase Flash Page routine |
| 0000'0104H | _NvmProgVerify | Pointer to Erase, Program & Verify Flash Page routine |
| 0000'0108H | _BmiInstallationReq | Pointer to Request BMI installation routine |
| 0000'010CH | _CalcTemperature | Pointer to Calculate chip temperature routine |
| 0000'0110H | _NvmEraseSector | Pointer to Erase Flash Sector routine |

Bootstrap Loaders (BSL) and User Routines

Table 20-5 User routines' in XMC1100 ROM

| XMC1100 ROM | | Description |
|--------------------|---------------------|---|
| Address | Content | |
| 0000'0114H | _NvmProgVerifyBlock | Pointer to Program & Verify Flash Block routine |
| 0000'0120H | _CalcTSEVAR | Pointer to Calculate target level for temperature comparison routine |

NVM-related functions (see [Section 20.3.1](#) and [Section 20.3.2](#)) return status indication as shown in [Table 20-6](#).

Table 20-6 Status indicators returned by NVM routines in XMC1100 ROM

| Status Indicator | | Description |
|-----------------------------|--------------|---|
| Symbolic name | Value | |
| NVM_PASS | 0001'0000H | Function succeeded |
| NVM_E_FAIL | 8001'0001H | Generic error |
| NVM_E_SRC_ AREA_EXCEEDED | 8001'0003H | Source data is not in RAM |
| NVM_E_SRC_ ALIGNMENT | 8001'0004H | Source data is not 4 Byte aligned |
| NVM_E_NVM_FAIL | 8001'0005H | NVM module can not be physically accessed |
| NVM_E_VERIFY | 8001'0006H | Verification of the written page not successful |
| NVM_E_DST_ AREA_EXCEEDED | 8001'0009H | Destination data is not (completely) located in NVM |
| NVM_E_DST_ ALIGNMENT | 8001'0010H | Destination data is not properly aligned |

The description below provides an overview of the features.

20.3.1 Erase Flash Page

XMC1100 Flash can be erased with granularity of one page = 16 blocks of 16 Bytes = 256 Bytes using this routine.

- Input parameter
 - logical address of the Flash Page to be erased, must be page aligned and in NVM address range (pageAddr)
- Return status (refer to [Table 20-6](#))
 - OK (NVM_PASS)

Bootstrap Loaders (BSL) and User Routines

- invalid address (NVM_E_DST_AREA_EXCEEDED, NVM_E_DST_ALIGNMENT)
- operation failed (NVM_E_FAIL, NVM_E_NVM_FAIL, NVM_E_VERIFY)
- Prototype
NVM_STATUS XMC1000_NvmErasePage (unsigned long pageAddr)

20.3.2 Erase, Program & Verify Flash Page

This function performs erase (skipped if not necessary), program and verify of selected Flash page.

- Input parameters
 - logical address of the target Flash Page (dstAddr)
 - address in SRAM where the data starts (srcAddr)
- Return status (refer to [Table 20-6](#))
 - OK (NVM_PASS)
 - invalid addresses (NVM_E_SRC_AREA_EXCEEDED, NVM_E_SRC_ALIGNMENT, NVM_E_DST_AREA_EXCEEDED, NVM_E_DST_ALIGNMENT)
 - operation failed (NVM_E_FAIL, NVM_E_NVM_FAIL, NVM_E_VERIFY)
- Prototype
NVM_STATUS XMC1000_NvmProgVerify (unsigned long srcAddr, unsigned long dstAddr)

20.3.3 Request BMI installation

This procedure initiates installation of a new BMI value. In particular, it can be used as well as to restore the state upon delivery for a device already in User Productive mode.

- Input parameter
 - BMI value to be installed (requestedBmiValue)
- Return status - only upon error, if OK the procedure triggers a reset respectively does not return to calling routine
 - wrong input BMI value (0001H)
- Prototype
unsigned long XMC1000_BmiInstallationReq (unsigned short requestedBmiValue)

20.3.4 Calculate chip temperature

This procedure calculates the current chip temperature as measured by the XMC1100 built-in sensor, based on data from Flash including trimming values and pre-calculated constants (refer to [Table 20-7](#)) and data from the actual measurement (read from Temperature Sensor Counter2 Monitor Register ANATSEMON).

- Input parameter
 - none
- Return status
 - chip temperature in degree Kelvin

Bootstrap Loaders (BSL) and User Routines

- Prototype
 unsigned long XMC1000_CalcTemperature (void)

20.3.5 Erase Flash Sector

XMC1100 Flash can be erased with granularity of one sector = 16 pages of (16 blocks of 16 Bytes) = 4K Bytes using this routine.

- Input parameter
 - logical address of the Flash Sector to be erased, must be in NVM address range (sectorAddr)
- Return status (refer to [Table 20-6](#))
 - OK (NVM_PASS)
 - invalid address (NVM_E_DST_AREA_EXCEEDED, NVM_E_DST_ALIGNMENT)
 - operation failed (NVM_E_FAIL, NVM_E_NVM_FAIL, NVM_E_VERIFY)
- Prototype
 NVM_STATUS XMC1000_NvmEraseSector (unsigned long sectorAddr)

20.3.6 Program & Verify Flash Block

XMC1100 Flash can be programmed and verified with granularity of one block (4 words of 4 Bytes) = 16 Bytes using this routine.

- Input parameter
 - logical address of the target Flash Block (dstAddr)
 - address in SRAM where the data starts (srcAddr)
- Return status (refer to [Table 20-6](#))
 - OK (NVM_PASS)
 - invalid addresses (NVM_E_SRC_AREA_EXCEEDED, NVM_E_SRC_ALIGNMENT, NVM_E_DST_AREA_EXCEEDED, NVM_E_DST_ALIGNMENT)
 - operation failed (NVM_E_FAIL, NVM_E_NVM_FAIL, NVM_E_VERIFY)
- Prototype
 NVM_STATUS XMC1000_NvmProgVerifyBlock (unsigned long srcAddr, unsigned long dstAddr)

20.3.7 Calculate target level for temperature comparison

This procedure - a kind of reverse of [Calculate chip temperature](#) - calculates the value which must be installed in ANATSEVAR register to get indication in ANATSESTATUS.TSE_CP_VAR_STAT bit when the chip temperature is above/below some target/threshold.

- Input parameter
 - threshold temperature in degree Kelvin - allowed range 223...423 (temperature)
- Return status
 - equivalent sensor threshold value for the temperature provided as input parameter

Bootstrap Loaders (BSL) and User Routines

- Prototype
unsigned long XMC1000_CalcTSEVAR (unsigned long temperature)

20.4 Data in Flash used by the User Routines

Table 20-7 shows the data in Flash which is used by the user routines in XMC1100.

Table 20-7 Basic Flash data for SSW and user SW in XMC1100

| Address | Length | Function | Target location |
|----------------------------------|--------|------------------------------------|-----------------|
| Start-up mode selection: | | | |
| 1000'0E00 _H | 2 B | Boot Mode Index (BMI) | --- |
| 1000'0E10 _H | 2 B | Inverse BMI | --- |
| Temperature-sensor related data: | | | |
| 1000'0F20 _H | 16 B | Temperature-sensor constant data 1 | --- |
| 1000'0F30 _H | 1 B | ANA_TSE_T1 | --- |
| 1000'0F31 _H | 1 B | ANA_TSE_T2 | --- |
| 1000'0F34 _H | 161 B | Temperature-sensor constant data 2 | --- |

Debug System

21 Debug System (DBG)

The debug system is an extension to the regular processor architecture. The XMC1100 Series Microcontrollers provide a complete hardware debug solution, with hardware breakpoint and watchpoint options. This allows high system visibility of the processor, memory and available peripherals. The debug functions are implemented with a standard ARM Cortex M0 configuration. Debug functions are integrated into the ARM Cortex-M0 processor architecture. The debug system supports serial wire debug and single pin debug interfacing.

21.1 Overview

The basic debug functionality of the Cortex-M0 debug system is limited to invasive debug and includes processor halt, single step, processor core register access, Reset and HardFault Vector Catch. Besides the hardware debug components unlimited software breakpoints are available. The Debugger can connect to the debug system via the Serial Wire Debug (SWD) or Single Pin Debug (SPD) interface port and uses CoreSight infrastructure and the regular access flow. This permits debugger to identify the processor and its debug capabilities. The debug system allows a full system memory access and access to zero-wait state system slaves via the internal debug access port (DAP) connected to the system bus matrix. This access is non-intrusive and a debugger can access the devices, including memory when the processor is halted or running. Core register full access is available, if the processor is halted. The System Control Space (SCS) provides debug through registers available. The Data Watchpoint Unit (DWT) provides two watchpoint register sets, each implement data address and PC based watchpoint functionality including comparator address masking. The processor BreakPoint Unit (BPU) provides four PC based breakpoint register. The system is accessible by the tool through DAP. DAP permits access to debug resources when the processor is running, halted, or held in reset. A processor enters Debug state if it is

configured to halt on a debug event, and a debug event occurs. The supported debug infrastructure can be identified by checking the ROM table.

21.1.1 Features

The accurate Debug and Trace System provides the following functionality:

- Serial Wire Debug Port (SWD) provides Serial Wire Debug, which allows to debug via 2 pins.
- Single Pin Debug (SPD) provides a debug capability via 1 pin.
- Processor halt, single-step, processor core register access
- Reset and HardFault Vector Catch.
- Software breakpoints
- Full system memory access
- 4 Hardware breakpoints supported
- 2 watchpoints supported

Note: Please refer to [ARMv6-M Architecture Reference Manual](#) for more detailed informations on the debug functionality.

21.1.2 Block Diagram

The Debug system block diagram is shown in [Figure 21-1](#).

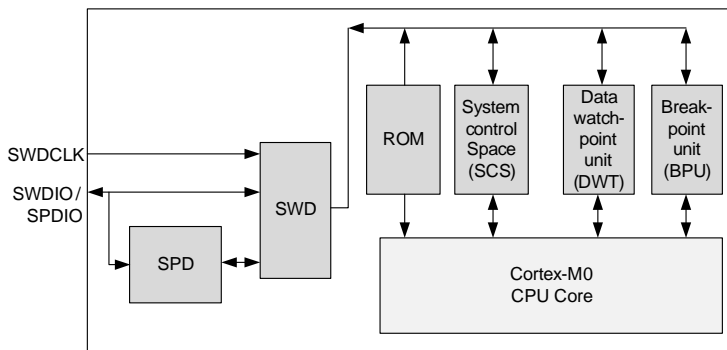

Figure 21-1 Debug and Trace System block diagram

21.2 Debug System Operation

The Debug System provides general debug options. Debug options are based on break points and CPU halt. Debug resources available are Data Watchpoint and Trace, Breakpoint unit, ROM table and the SCS system control block and debug control block. Debug capabilities can be accessed by a debug tool via Serial Wire Debug interface

(SWD) or Single Pin Debug (SPD). The selection of the access protocol (SWD or SPD) is done by BML mode setting.

21.2.1 System Control Space (SCS)

The SCS is the area where the debugger can have direct access to the memory mapped register debug register. The debug resources together with the debug register in the SCS are accessible through the DAP interface. Accessible resources are for example system control and ID registers including system control block. Additionally the system timer and the interrupt controller (NVIC) can be accessed via the SCS.

21.2.2 Data Watchpoint and Trace (DWT)

The DWT unit provides an external Program Counter (PC) sampling capability based on PC sample register and comparators, that support watchpoints for address matching and PC watchpoints for instruction address matching. The PC sampling feature and watchpoint support operate independently of each other and a watchpoint event is asynchronous to the instruction that caused it. The XMC1100 supports two watchpoints, each supporting compare, mask and function registers. Watchpoint events result in a processor halt and enters the processor system into debug state. Data address matching results in a creation of a watchpoint event. Instruction address matching in a creation of a PC watchpoint event. The DWT register are accessible through the DAP interface.

A DWT program counter sample register permits a debugger to periodically sample the PC without halting the processor and allows coarse grained profiling. The PC sampling feature and the watchpoint support operate independently of each other. The register is defined so that a debugger can access it without changing the behavior of any code currently executing on the device.

The recommended mechanism for generating a breakpoint on a single instruction address is to use the BPU. The DWT based mechanism must be used to generate a PC matching event on a range of addresses. The debug return address value for a watchpoint event must be that of an instruction to be executed after the instruction responsible for generating the watchpoint.

21.2.3 Break Point Unit (BPU)

The Breakpoint (BKPT) instruction provides software breakpoints. It can cause a running system to halt depending on the debug configuration. A BKPT is a synchronous debug event, caused by execution of a BKPT instruction or by a match in the BPU. A BKPT causes the processor to enter debug state. The Debug tool can use this situation to investigate the system state when the instruction at a particular address is reached. The BPU provides support for breakpoint functionality on instruction fetches, based on instruction address comparator. The M0 provides four breakpoint comparator registers. Each breakpoint comparator register includes its own enable bit. The comparators match

instruction fetches from the Code memory region and operate only on instruction read accesses. The comparators do not match data read or data write access. Address matching is available on the upper half word, lower half word or both half words. Potential reasons for a debug event are a debug halt, a BKPT, a DWT trap and Vector CATCH.

21.2.4 ROM Table

To identify the Cortex-M0 processor with the respective Debug System components the debugger locates and identifies the ROM table. ROM table Identification values are predefined and contain pointers to the SCS, BPU and DWT. Each of the debug modules requires its own ROM table and indicate whether the block is present. The ROM table can be accessed through the DAP interface.

21.2.5 Debug tool interface access - SWD

The tool access based on SWD must use a connection sequence, to ensure that hot-plugging the serial connection does not result in unintentional transfer. The connection sequence ensures that the SWD is synchronized correctly to the header. The sequence consists of a sequence of 50 clock cycles data = 1s. This connection sequence is also used as a line reset sequence. The protocol requires that any run of 50 consecutive 1s on the data input is detected as line reset, regardless of the state of the protocol. After the line reset the debugger reads IDCODE register, which gives confirmation that correct packet frame alignment has been achieved.

21.2.5.1 SWD based transfers

The SWD interface requires to continue the clock for a number of cycles after the data phase of any data transfer. This ensures the transfer is completely clocked through the SWD. The transfer completion can be achieved by an immediate start of a new SWD operation, continuous clocking of SWD interface until the host starts a new SWD operation or after the data parity bit the clock is continued for at least 8 more clock rising edges, before stopping the clock.

Each sequence of operation on the serial wire consists of two or three phases and is defined from debugger point of view. The package request and acknowledge response phases are always there. The data transfer phase is only present when either data read or data write request is followed by a valid acknowledge response or the Overrun Detect flag is set.

The SWD protocol applies a simple parity check to all packet request and data transfer phases. On a packet request the parity check is made over the four bit header. On a data transfer the parity check is made over the complete 32 data bits. The parity is added directly after the packet request and after the data transfers. The parity bits are not included in the parity calculation.

Serial Wire Debug protocol operation

The SWD protocol supports the following operations:

- **Write operation** including OK response (3-Phases: 8-bit write packet request, 3-bit OK ACK, 33-bit data write including 1-bit parity at the end)
- **Read operation** including OK response (3-Phases: 8-bit read packet request, 3-bit OK ACK, 33-bit data read including a 1-bit parity at the end).
- **WAIT response** to read or write operation request (2 Phases: 8-bit read or write packet request, 3-bit WAIT ACK response)
- **FAULT response** Read or Write operation (2-Phases: 8-bit read or write packet request, 3bit FAULT ACK response)
- **Protocol error** sequence occurs when target failed to return a ACK response (1 Phase: 8-bit Packet request - line not driven by target for 32 bit cycles)

Note: A single-cycle turnaround period between the operation phases is required, for the transfer direction change only. If there is no transfer direction change, no turnaround period is introduced. If the protocol ends with a data transfer towards the debugger a turnaround period is introduced. After the single-cycle turnaround time the protocol must be proceeded.

21.2.5.2 SWD based errors

On the SWD interface protocol errors can occur. These errors might be detected by the parity checks on the data. A message header error can be detected by a parity error. A debugger not receiving a response or a port does not respond to the message, the debugger must back off. During the back off mechanism the debugger does read the IDCODE register and ensures the Debug Port is responsive and then retries the original access.

Errors can be returned by the DAP itself or might come from a debug resource. When an error occurs the error bit remains sticky until cleared. A debugger must check the error status after performing a series of transaction to be aware of an error.

Error conditions within the SWD interface are recorded using sticky flags. Potential errors are read and write errors, overrun detection, protocol errors. When the sticky bit is set to 1 it remains set until it is explicitly cleared to 0. When an error is flagged the current transaction is completed and any additional access port access transaction is discarded until the sticky flag is cleared to 0. A debugger must check periodically the Control/Status register after performing a series of transactions to detect the error.

A read and write error might occur within the DAP or come from the resource being accessed. Additionally a read or write error might be generated if the debugger makes an access port transaction request while the debugger power domain is powered down.

An overrun error might be detected on a sequence of transactions. Therefore the debugger must check after each sequence. The Overrun detection mode can be left by clearing the STICKYORUN and ORUNDETECT.

On the Serial Wire Interface protocol errors can occur, for example because of wire-level errors. These errors might be detected by the parity checks of data. If the SWD interface detects a parity error in a message header of the debug message the error is reflected. If the interface does not receive a response to a message, the debugger must back off. It must then requires a read of the IDCODE register, to ensure the debug port is responsive, before retrying the original access, again. If the SWD detects a parity error in the data phase of a write transaction, it sets the sticky write data error flag (WDATAERR) in the control and status register. Subsequent accesses from the debugger, other than IDCODE, CTRL/STAT or ABORT, result in a FAULT response.

21.2.6 Debug tool interface access - Single Pin Debug (SPD)

The SPD protocol based tool interface access allows to debug the system using a single pin only. The bit frequency is 2 MHz and allows an effective SWD telegram of 1.4 Mbits/s. The protocol is very robust against clock deviations between tool and device.

The SPD protocol encodes the SWD protocol bits with the distance between the SPD signal edges. A SWD value of '0' is encoded with a short distance of 0.5 μ s, a value of '1' with a distance of 1 μ s. This encoding is used in both transfer directions. Initially the SPD signal level always start with a positive SPD signal pulse with 1 μ s width, encoded SPD start bit, which is not part of the SWD protocol. The transmission of the rest of the telegram will be independent of the edge direction. As the protocol starts with a logic one start bit detection it is recommended to finish the protocol with a logic 0 signaling level. If the SPD signal level is high after the last bit of the telegram, that tool to add at '0' bit with a negative edge after 0.5 μ s. This can be achieved by the tool transferring an odd number of bits.

SWD has a clean request response protocol, where the tool is always the requestor and the device executes and sends a response. So the SWD module will change the direction as defined by the SWD protocol operations ([Section 21.2.5.1](#)).

Figure 21-2 SPD Encoding Example

As a basic example a simple transfer is described in Figure before. Initially (1) the SPD module is in IDLE state. During IDLE state the SPD module does not generate a clock to the SWD module. At point (2) the SPD detects a rising edge and moves to a receive state. The first rising edge of the protocol is a start bit for the SPD module only and is not transferred to the SWD module. The following bits are the SWD header information and transferred to the SWD module. At point (5) a logic 1 shown and at (6) a logic zero. At the time the protocol direction is changed (which means for the implementation to go through IDLE state) the clock to SWD is switched off as shown in state (7). The SPD module requires to end on a Low signal value therefore it is required to have an odd number of bits moved into the interface.

Protocol transfer requirements between SWD and SPD module

The data transfer to and from SWD protocol is single bit based on the SWD clock. The SWD clock is generated by the SPD module and directly derived from the transferred bit. In RECEIVE direction the SPD module transfers the data to the SWD module bit wise, with one clock cycle per bit received.

The SPD module switches off SWD clock when going through module IDLE.

The Debugger adds a SPD start bit in front of the SWD telegram when it writes data to the device (from SPD point of view, RECEIVE). The SPD RECEIVE start bit is not transferred to the SWD module. The RECEIVE start bit is in front of the original SWD protocol on every new RECEIVE start, which is in front of the SWD header and again in front of debugger write data. Additionally the SPD module requires in RECEIVE direction a protocol to end with a logic zero signal level, which is achieved by an odd number of bits transferred by the tool. Based on the SWD protocol this is already achieved in the header phase by adding the described SPD start bit. During acknowledge phase as this phase does have 3 bits only. During the protocol data phase the Debugger has to add one more zero bit. (SPD Start bit, 32-bit data, parity bit, SPD odd bit as logic Zero).

As the SWD protocol requires in RECEIVE direction at least 8 clocks at the end of the data transferred to finish the protocol operation the Debugger has to add 9 logic zeros to the protocol (8 for this requirement and 1 to have an odd number).

SPD protocol based tool Interaction

All SPD communication is initiated by the tool. The tool will send a SWD header encoded to a SPD telegram (header) and then switches the SPD signal direction to input and wait for the acknowledge from the device.

SPD Receive:

Based on a low level the tool starts the protocol with SPD start bit. The start bit is indicated with a rising edge and a signal duration of 1 μ s. The following bits are based on the SWD protocol sequence.

The start sequence: SPD start bit + SWD HEADER + 0 Bit + 0 Bit (the two additional 0 bits at the end are required to achieve a low level at the signaling line.).

After receiving the header, the SWD will output his acknowledge response. Thus, SPD will change from RECEIVE to IDLE to SEND and ACKto IDLE again.

Leaving IDLE to RECEIVE state to transfer write data the start bit from tool is also required.

The SPD start bit must be a logic one with the defined time duration of a logic one. Is the signal duration longer it turns into a timeout situation. Is the signal duration shorter the start bit is not recognized.

The debug tool not sending data continuously in SPD RECEIVE direction, generates a Timeout in SPD module, which brings it to IDLE mode again. Starting from IDLE state the tool is required to provide SPD start bit for a new communication. A timeout is recognized after 1.4 μ s.

A permanent write (SPD RECEIVE) allows to proceed the protocol without SPD start bit. In this case the SPD interface remains in RECEIVE state and only the SWD receive protocol has to be performed. In this case the SWD header has to start with a logic 1 as defined by the SWD protocol.

SPD SEND:

The tool is required to end a RECEIVE at low level. Based on the low level the SEND start is indicated by a rising edge. SEND has to end with a signal low level, too.

IDLE:

From RECEIVE to IDLE - driven by SPD or by timeout.

From SEND to IDLE - driven by SWD module caused by direction change .

Time to switch from RECEIVE to SEND is between 375 and 500 ns and always goes through IDLE phase. The tool must change from write (SPD RECEIVE) to read (SPD SEND) direction within 375 ns. SEND always starts with a rising edge.

21.2.7 Debug accesses and Flash protection

The XMC1100 Flash implements read protection for sector 0 only. All other sectors can be read. Additionally a user configuration erase and write protection is available, which allows to protect Flash content from unintended writes or erase. Special care is taken, that the debugger can't bypass this protection.

Because of this, per default and after a system reset the debug interface is disabled. The Boot Mode Index (BMI) determines if the debug mode can be entered and the debug interface enabled at the end of the SSW.

Before the BMI is configured to user productive mode a change of BMI to arbitrary value is supported, afterwards BMI can only be restored to its default value, which does not enable debug access.

Besides the BMI configuration the Debug system supports a protection mechanism which prevents a debug access to the system address area during the time startup software (SSW) is running. Firmware controls the debug access, based on register setting.

Software based Breakpoints are supported, but prevented during SSW.

21.2.8 Halt after reset

There are two possibilities to perform a halt after reset. The first possibility is Infineon specific and allows to perform a CPU halt after "power on"/"master" reset (HAR) at the very first instruction of the Application code. The HAR activation is based on BMI settings and SSW executing endless loop, allowing a debugger to take control over the device. A defined configuration sequence driven by the connected debug tool is required in this case. The second possibility is the regular ARM flow halt after reset, which is based on breakpoints and a system reset. This halt after reset is also named "Warm Reset". In both cases the ARM system can not be accessed for security reasons from the debug port during the time SSW is running, as the physical pins are not available during that time. Based on the BMI setting the debug capability can be enabled at the end of the SSW by firmware. The default BMI configuration does not enable debug access.

21.2.8.1 HAR

The BMI can be configured to allow a HAR (UMHAR) at the end of the SSW, which always requires a power on reset to be executed. A new BMI configuration to BMI.UMHAR (User Mode with debug enabled and HAR) requires to perform a master reset to boot in UMHAR mode.

At a HAR (Cold Reset situation), the system comes from a PORST (or Master Reset) . To achieve a HAR, the tool has to register (CDBGPWRUPREQ) and enable (DHSCR.C_DEBUGEN) the debug system. Additionally it has to halt (DHCSR.C_HALT) the CPU and manipulate the PC (Program Counter) to point to the start address of the user code. The debugger registration and debug system enable is possible at the end of

Debug System (DBG)

the firmware, where firmware is waiting for a tool registration. During SSW execution the debugger as no access capability and cannot set the enabling bits CDBGPWRUPREQ, C_DEBUGEN or halt the CPU. The address of the user code start address can be read from address 0x10001004 in user Flash. It is recommended to check the Boot Mode Index BMI.HWCFG bit for UMHAR before manipulating the PC.

The following Figure (Figure HAR - Halt After Reset) shows the software flow based on the modules participating to the HAR.

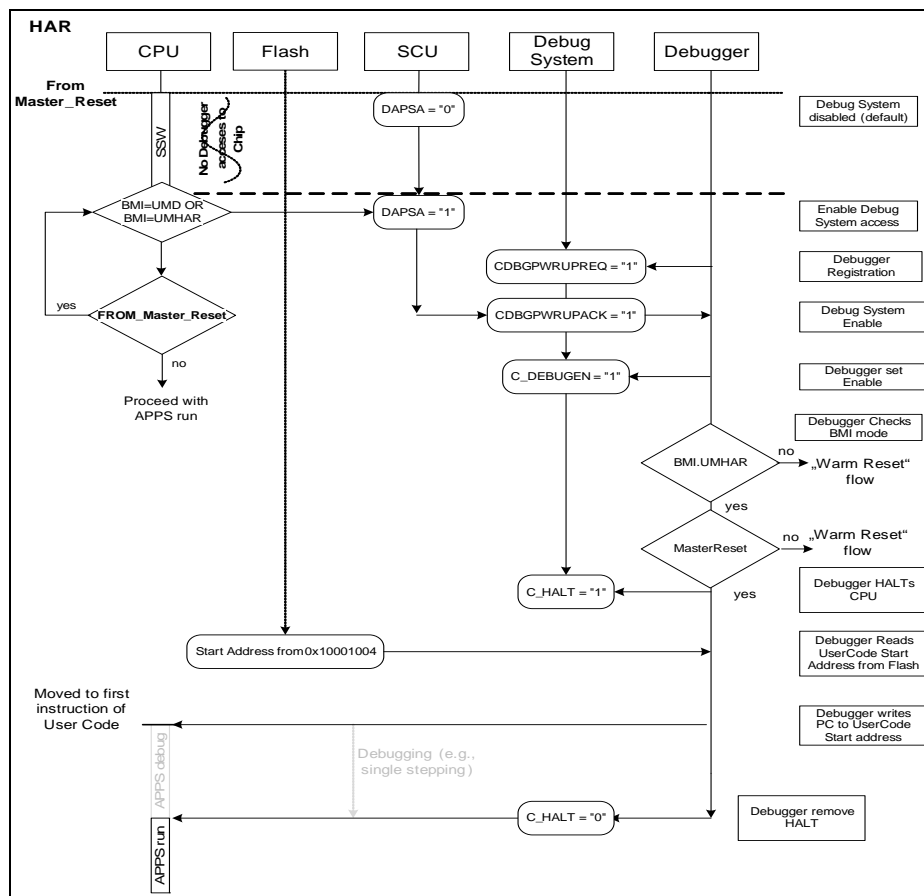

Figure 21-3 HAR - Halt After Reset Flow

21.2.8.2 Warm Reset

A halt after system reset (Warm Reset) can be achieved by programming a break point at the first instruction of the application code. Additionally the CDBGPWRUPREQ (tool registration) and the C_DEBUGEN has to be set by the debugger. After a system reset, the HAR situation is not considered, as the reset is not coming from PORST (Master_Reset).

Note: The CDBGPWRUPREQ and C_DEBUGEN does not have to be set after a system reset, if they have already been set before and the debugger remains registered. The bits are not affected by the system reset.

A tool hot plug situation allows to debug the system by enabling the CDBGPWRUPREQ and the C_DEBUGEN register. It is recommended to check the Boot Mode Index BMI.HWCFG. The Warm Reset flow can be done in both BMI modes, UMD (User mode with debug enabled) and UM HAR. In both cases the "Warm Reset" flow is based on breakpoint setting and system reset afterwards.

In general after a tool hot plug break points can be set or the CPU can directly be HALTED and stops at the actual program stage. To stop at the very first instruction of the user code the tool has to fire a system reset after setting the breakpoint there.

The following Figure (Figure Hot Plug and Warm Reset) illustrates the debug tool HOT PLUG situation or the Halt after Warm Reset (system reset) and how to proceed to come to a Halt situation.

mode. Per default a peripheral is not sensitive on a suspend request. Sensitivity can be configured based on the system use case.

It can be decided at the peripheral to support a Hard Suspend or a Soft Suspend. At a Hard Suspend situation the clock at the peripheral is switched off immediately, without waiting on acknowledge from the module. At a soft suspend the peripheral can decide when to suspend. Usually at the end of the actual active transfer.

A Watchdog timer is only running when the suspend bus is not active. This is particularly useful as it can't be serviced by a halted CPU. A configuration option is available, which allows to enable the Watchdog timer also during suspend. This allows to debug Watchdog behavior, if a debugger is connected.

The user has to ensure, that always only those peripherals are sensitive to suspend, which are intended to be. To address this, each peripheral supporting suspend does have an enable register which allows to enable the suspend feature. The following table ([Table 21-1](#)) shows the peripherals, supporting or not supporting peripheral suspend or detailed information on the peripheral suspend behavior during soft suspend can be found at the respective peripheral chapter.

Table 21-1 Peripheral Suspend support

| Peripheral | supported | default mode | Hard Suspend | Soft Suspend |
|------------|-----------|--------------|--------------|--------------|
| RTC | yes | not active | yes | no |
| USIC | yes | not active | no | yes |
| CCU4 | yes | not active | yes | yes |
| WDT | yes | active | yes | no |
| VADC | yes | not active | yes | yes |
| PRNG | no | - - - | - - - | - - - |

Note: Enable debug suspend function in the user initialization code after every reset. In addition the user has to consider debug suspend register at peripherals can only be configured after the clock of the module is enabled via CGATCLR0 register.

Important tool provider note:

The peripheral suspend logic is connected to the system reset. A system reset activation results in a peripheral suspend configuration loss. Therefore the suspend configuration at the peripherals "outlasting" a system reset, requires the tool to reconfigure the suspend configuration after system reset. This is achieved by shadowing the user peripheral suspend configuration in the tool and set a HW breakpoint at the first instruction of use code, if the suspend function is activated. After the CPU halts at that breakpoint the tool has to reconfigure the suspend configuration at the peripheral, as it has been configured before the system reset.

Note: Suspend activation results in losing one HW breakpoint, as it is used by the tool to handle the suspend reconfiguration after system reset.

A debug tool should offer the peripheral suspend reconfiguration after system reset with an option to proceed Usercode without an user interaction requirement after tool reconfiguration or remain stopped at first line of user code and wait for user action.

(The user configures the desired suspend behavior only once and the tool stores the configuration to have it present for a automatic reconfiguration after a system reset.)

21.2.10 Debug System based processor wake-up

The debugger can wake-up a processor in sleep mode (sleep and deep sleep mode). The wake-up is based on a new pending interrupt event from the debug system, which is a HALT. The interrupt event does also wake-up the processor, if the interrupt is disabled or has insufficient priority to cause exception entry. The interrupt wake-up mode is derived by the NVIC (Programmable Multiple Priority Interrupt System) available in the processor system. The debugger is able to register, enable the Debug System and HALT the CPU also in sleep and deep sleep mode.

Note: The wake-up from deep-sleep mode via debugger halt is only supported using SWD interface. A wake-up from deep-sleep based on SPD interface is not supported.

21.2.11 Debug Access Server (DAS)

The DAS API provides an abstraction of the physical device interface for tool access. The key paradigm of DAS is to read or write data in one or several address spaces of the target device.

DAS Features

- Standard interface for all types of tools
- Efficient and robust methods for data transfer
- Several independent tools can share the same physical interface
- Infineon's DAS miniWiggler support SWD and SPD.

Note: DAS is not XMC1100 specific. It can be used for all Infineon 8-, 16, and 32-bit microcontrollers with DAP, SWD, SPD or JTAG interface. For more information refer to www.infineon.com/DAS.

21.2.12 Debug Signals

XMC1100 MC product family provides debug capability using ARM M0 Debug port SWD or the Infineon proprietary SPD. The SWD Port has 2 interface signals (Clock + Bidirectional data). The SPD port has one interface signal (SPDIO - bidirectional data) with an overlay of SWD interface SWDIO pin.

Table 21-2 SWD toplevel IO signal

| Signal | Direction | Function |
|--------|-----------|---|
| SWDCLK | I | Serial Wire Clock. This pin is the clock for debug module when running in Serial Wire debug mode. |
| SWDIO | I / O | Serial Wire debug data IO. Used by an external debug tool to communicate with and control the Cortex-M0 debug system. |

The HALTED and EDBGREQ signals can be used to halt the CPU based on an external event. This allows to halt an external hardware synchronously with the CPU. The halt can be recognized by the external hardware based on the HALTED output. This can be used for example to synchronize with an logic analyzer and request a breakpoint or in a multi CPU scenario.

21.2.12.1 Internal pull-up and pull-down on SWD/SPD pins

It is a requirement to ensure none floating SWD/SPD input pins, as they are directly connected to flip-flops controlling the debug function. To avoid any uncontrolled I/O voltage levels internal pull-up and pull-downs on SWD/SPD input pins are provided.

- SWDIO/SPD: Internal pull-up
- SWCLK: Internal pull-down

21.2.13 Reset

The debug system register bits are reset by Power-on reset. Other reset in the system do not have an effect on the debug register, if the tool is registered.

21.3 Debug System Power Save Operation

The Debug System is in the “always-on” power domain, which allows to connect the debugger to the device. The Debug System does not support any special power mode or power save operation. The power supply of the Debug System is directly connected to the main chip part including the system components.

21.4 Service Request Generation

The debugger can set DHCSR.C_MASKINTS to 1 to prevent PendSV, SysTick and external configured interrupts from occurring.

21.5 Debug behavior

The Debug System is based on events. Whereas events are an entry to debug state, if halting debug is enabled. Debug events available are:

- Internal halt request
- Breakpoint
- Watchpoint
- Vector catch
- External debug request based on

The following events are synchronous debug events:

- Breakpoint debug events, caused by execution of a BKPT instruction
- Breakpoint debug events, caused by execution of a match in the BPU
- Vector catch debug events
- Step debug events (DHCSR.C_STEP)

The following events are asynchronous debug events:

- Watchpoint debug events, including PC match watchpoints
- Halt request debug event (DHCSR.C_HALT)
- External signal based debug request event (EDBGRQ signal)

Asynchronous debug events do have a lower prioritization then synchronous generated events. An instruction can generate a number of synchronous debug events. It also can generate a number of asynchronous exceptions.

The Debug Fault Status register (DFSR) contains a status bit for each debug event. The bits are write-one-to-clear. These bits are set to 1 when a debug event causes the processor to halt or generate an exception. The bits are also updated if the event is ignored.

Software must write 0xA05F to the DHCSR.DBGKEQ register in order to be able to have debug support available from CPU side.

21.6 Power, Reset and Clock

The requirements for power, reset and clock are derived from ARM.

21.6.1 Power management

There is no power management implemented for the debug system. . Nevertheless the tool does has to follow the regular tool flow by setting the CDBGPWRUPREQ in order to register the tool.

21.6.2 Debug System reset

The SWD register are in the power on reset (PORST) domain.

The Debug logic is reset by system reset, if no tool is connected to chip and therefore not registered, which is indicated by **CDBGPWRUPREQ** not set.

Processor reset

A processor or warm reset (SYSRESETn) initializes the majority of the processor, excluding debug logic, BKPT unit, DWT unit and SCS.

PowerOn reset

PORESETn reset initializes the SWD access port, the AHB-AP logic and all other debug system related functions.

Normal operation

During normal operation the resets PORESETn and SYSRESETn are deasserted.

Processor reset affects Debug System

A System reset also affects the Debug System, if a tool is not registered. The tool registration is reflected by an activation of the register bit CDBGPWRUPACK, which activates by a debugger enabling the CDBGPWRUPREQ. .

21.6.3 Debug System Clocks

The Debug system clock is called DCLK and is derived directly from SCLK (free running clock). DCLK must always be driven while a debugger is connected.

21.7 Initialization and System Dependencies

21.7.1 ID Code

Available ID Code is used by a debug tool to identify the available debug components during tool setup.

Table 21-3 ARM CoreSight™ Component ID code

| ID | Value | Description |
|-------|------------------------|------------------|
| SW_DP | 0BB1 1477 _H | The ARM SW-DP ID |

21.7.2 ROM Table

To identify Infineon as manufacturer and XMC1100 as device, the ROM table has to be read out. The format of the ROM table is illustrated in [Table 21-4](#).

Table 21-4 Peripheral ID Values of XMC1100 ROM Table

| Name | Offset | Value¹⁾ | Bits | Reference | Infineon JTAG ID Code |
|-------------|------------------|---------------------------|-----------------------|---|---|
| PID0 | FE0 _H | XXXXXXXX _B | [7:0] | Part Number [7:0] | DBGROMID [19:12] |
| PID1 | FE4 _H | 0001XXXX _B | [7:4] [3:0] | JEP106 ID code [3:0] Part Number [11:8] | DBGROMID [4:1] DBGROMID [23:20] |
| PID2 | FE8 _H | XXXX1100 _B | [7:4] [3] [2:0] | Revision JEDEC assigned ID fields JEP106 ID code [6:4] | DBGROMID [31:28] '1' DBGROMID [7:5] |
| PID3 | FEC _H | 00000000 _B | [7:4] [3:0] | RevAnd, minor revision field Customer-modified block (if non-zero) | |
| PID4 | FD0 _H | 00000000 _B | [7:4] [3:0] | 4KB count JEP106 continuation code | 4KB count DBGROMID [11:8] |

1) For "X" values please refer to Data Sheet

The ROM table values representing Infineon Part Number, JEP106 and Revision number can be checked in the SCU chapter.

21.8 Debug System Registers

Registers Overview

The absolute register address is calculated by adding:

The DWT, BPU, ROM table, DCB and debug register in the SCS are accessible memory mapped by the debugger and also from the CPU.

Table 21-5 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|---------------------|
| DWT | E000 1000 _H | E000 1FFF _H | Data Watchpoint |
| BP | E000 2000 _H | E000 2FFF _H | Breakpoint Unit |
| SCS | E000 E000 _H | E000 EFFF _H | SCS (here DBG CTRL) |
| ROM | E00F F000 _H | E00F FFFF _H | ROM table area |

21.8.1 DFSR - Debug Fault Status Register

SCS_DFSR

The DFSR registers provides the top level reason why a debug event has occurred. Writing 1 to a register bit clears the bit to 0. A read of the HALTED bit by an instruction executed by stepping returns an UNKNOWN value.

SCS_DFSR

Debug Fault Status Register (D30_H) **Reset Value: 0000 0000_H**

| | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|----------|--------|------|---|
| HALTED | 0 | rw | HALTED Indicates a debug event generated by a C_HALT or C_STEP request, triggered by a write to the DHCSR. 0 _B no active halt request debug event. 1 _B halt request debug event active. |
| BKPT | 1 | rw | BKPT Indicates a debug event generated by BKPT instruction execution or a breakpoint match in the BPU. 0 _B no breakpoint debug event. 1 _B at least one breakpoint debug event. |
| DWTTRAP | 2 | rw | DWTTRAP Indicates a debug event generated by the DWT. 0 _B no debug events generated by the DWT. 1 _B at least one debug event generated by the DWT. |
| VCATCH | 3 | rw | VCATCH Indicates whether a vector catch debug event was generated. 0 _B no vector catch debug event generated. 1 _B vector catch debug event generated. <i>Note: The corresponding FSR shows the primary cause of the exception.</i> |
| EXTERNAL | 4 | rw | EXTERNAL Indicates an asynchronous debug event generated because of EDBGRRQ being asserted. 0 _B no EDBGRRQ debug event. 1 _B EDBGRRQ debug event. |
| 0 | [31:5] | r | Reserved |

21.8.2 DHCSR - Debug Halting Control and Status Register

SCS_DHCSR

Controls halting debug. When C_DEBUGEN is set to 1, C_STEP and C_MASKINTS must not be modified when the processor is running (S_HALT is 0 when the processor is running). When C_DEBUGEN is set to 0, the processor ignores the values of all other bits in this register.

Debug System (DBG)

A separate register is represented below for read and write as the function changes at some bits access based.

SCS_DHCSR

21.8.3 DCRSR - Debug Core Register Selector Register

SCS_DCRSR

The DCRSR together with DCRDR (Debug Core Register Data Register) provides debug access to the ARM core register and special-purpose registers. A write to DCRSR specifies the register to transfer, whether the transfer is a read or a write, and starts the transfer. This register is only accessible in Debug state.

SCS_DCRSR

Debug Core Register Selector Register (DF4_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|--------|----|----|----|---------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| REGSEL | [4:0] | rw | REGSEL - Specifies the ARM core register or special-purpose register to transfer 00000 _B - 01100 _B ARM core register R0-R12. For example, 0b00000 specifies R0 and 0b00101 specifies R5 01101 _B The current SP. See also values 0b10001 and 0b10010. 01110 _B LR. 01111 _B Debug Return Address. 10000 _B xPSR. 10001 _B Main stack pointer, MSP. 10010 _B Process stack pointer, PSP. 10100 _B Bits[31:24] Control; Bits[23:8] Reserved; Bits[7:0] PRIMASK. In each field, the valid bits are packed with leading zeros. For example DCRDR [31L26] is 0b000000. |
| REGWnR | 16 | rw | REGWnR specifies the type of access for the transfer 0 _B read. 1 _B write. |
| 0 | [31:17], [15:5] | r | Reserved |

21.8.4 DCRDR - Debug Core Register Data Register

SCS_DCRDR

The DCRDR works with the DCRSR (Debug Core Register Selector Register). The DCRDR provides debug access to the ARM core registers and special-purpose registers. The DCRDR is the data register for these accesses.

SCS_DCRDR

Debug Core Register Data Register (DF8_H) **Reset Value: xxxx xxxx_H**

| Field | Bits | Type | Description |
|--------|--------|------|--|
| DBGTMP | [31:0] | rw | DBGTMP - Data temporary cache, for reading and writing register. This register is UNKONWN: <ul style="list-style-type: none"> on reset when DHCSR.S_HALT = 0 when DHCSR.S_REGRDY = 0 during execution of a DCRSR based transaction that updates the register. |

21.8.5 DEMCR - Debug Exception and Monitor Control Register

SCS_DEMCR

The DEMCR purpose is to manage vector catch behavior and enable the DWT.

A Power-on reset sets all register bits to 0. A local reset sets DWTENA to 0 but does not affect VC-HARDERR or VC_CORERESSET.

SCS_DEMCR

Debug Exception and Monitor Control Register (DFC_H) Reset Value: 0000 0000_H

|------------------|------|------|---|
| VC_CORERES ET | 0 | rw | VC_CORERESET - Enable Reset Vector Catch. This causes a Local reset to handle a running system 0 _B Reset Vector Catch disabled. 1 _B Reset Vector Catch enabled. <i>Note: If DHCSR.C_DEBUGEN is set to 0, the processor ignores the value of this bit.</i> |
| VC_HARDERR | 10 | rw | VC_CORERESET - Enable Reset Vector Catch. This causes a Local reset to halt a running system. 0 _B halting debug trap disabled. 1 _B halting debug trap enabled. <i>Note: If DHCSR.C_DEBUGEN is set to 0, the processor ignores the value of this bit.</i> |
| DWTENA | 24 | rw | DWTENA - Global enable for all features configured by the DWT unit. 0 _B DWT disabled. 1 _B DWT enabled. <i>Note: When DWTENA is set to 0 DWT registers return UNKNOWN values on reads. In addition the processor ignores writes to the DWT while DWTENA is 0.</i> |

| Field | Bits | Type | Description |
|----------|---|------|-----------------|
| 0 | [31:25], [23:16], [15:11], [9:1] | r | Reserved |

21.8.6 DWT_CTRL - Data Watchpoint Control Register

DWT_CTRL

The DWT_CTRL register defines the number of comparators implemented.

DWT_CTRL

Debug Halting Control and Status Register (000_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| NUMCOMP | [31:28] | rw | Number of comparators available 0000 _B No comparator support. |
| 0 | [27:0] | r | Reserved |

21.8.7 DWT_PCSR - Program Counter Sample Register

DWT_PCSR

The DWT_PCSR register samples the current value of the program counter. The register is UNKNOWN on reset.

DWT_PCSR

Program Counter Sample Register (01C_H)

Reset Value: xxxx xxxx_H

| Field | Bits | Type | Description |
|------------------|--------|------|--|
| EIASAMPLE | [31:0] | rw | EIASAMPLE Executed instruction address sample register |

21.8.8 DWT_COMPx - DWT Comparator register

DWT_COMPx

The DWT_COMPx register provides a reference value for use by comparator x. The value is UNKNOWN on reset. DWT_CTRL.NUMCOMP defines the number of implemented DWT_COMPx register, from 0 to (NUMCOMP-1).

The DWT_COMP [1 .. 0] register are implemented.

DWT_COMP0

DWT Comparator register 0 (020_H)

Reset Value: xxxx xxxx_H

DWT_COMP1

DWT Comparator register 1 (030_H)

Reset Value: xxxx xxxx_H

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| COMP | [31:0] | rw | COMP Reference value for comparison |

21.8.9 DWT_MASKx - DWT Comparator Mask Register

DWT_MASKx

The DWT_MASKx register provides the size of the ignore mask applied to the access address range matching by comparator x. The value is UNKONWN on reset. DWT_CTRL.NUMCOMP defines the number of implemented DWT_COMPx register, from 0 to (NUMCOMP-1).

The DWT_MASK [1 .. 0] register are implemented.

DWT_MASK0

Debug Halting Control and Status Register (24_H)

Reset Value: 0000 0000_H

DWT_MASK1

Debug Halting Control and Status Register (34_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| MASK | [4:0] | rw | MASK The size of the ignore mask applied to address range matching. Writing all ones to this field and reading it back can be used to determine the maximum mask size supported (not all mask bit must be implemented). |
| 0 | [31:5] | r | Reserved |

21.8.10 DWT_FUNCTIONx - Comparator Function Register

DWT_FUNCTIONx

The DWT_FUNCTIONx register controls the operation of the comparator DWT_COMPx register. DWT_CTRL.NUMCOMP defines the number of implemented DWT_FUNCTIONx registers, from 0 to (NUMCOMP-1).

The DWT_FUNCTION [1 .. 0] register are implemented.

DWT_FUNCTION0

Comparator Function Register (28_H) **Reset Value: 0000 0000_H**

DWT_FUNCTION1

Comparator Function Register (38_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|----------|-------|------|---|
| FUNCTION | [3:0] | rw | FUNCTION Select action on comparator match- 0000 _B Disabled. 0001 _B Reserved. 0010 _B Reserved. 0011 _B Reserved. 0100 _B PC watchpoint event - input laddr. 0101 _B Watchpoint event - input Daddr (read only) 0110 _B Watchpoint event - input Daddr (write only) 0111 _B Watchpoint event - input Daddr (read/write) 1xxx _B reserved <i>Note: This field is set to 0 on a Power-on reset.</i> |

| Field | Bits | Type | Description |
|----------------|--------------------------------|------|--|
| MATCHED | 24 | rw | MATCHED Comparator match. It indicates that the operation defined by FUNCTION has occurred since the bit was last read. 0_B the associated comparator has matched. 1_B the associated comparator has not matched. <i>Note: Reading the register clears this bit to 0.</i> |
| 0 | [31:25], [23:16], [15:4] | r | Reserved |

21.8.11 BP_CTRL - Breakpoint Control Register

BP_CTRL

The Breakpoint Control Register provides BPU implementation information and the global enable for the BPU.

BP_CTRL

Breakpoint Control Register (000_H) Reset Value: 0000 0040_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|-----|-----------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | NUM_CODE | | | | 0 | | KEY | EN BLE |
| r | | | | | | | | r | | | | r | rw | rw | |

| Field | Bits | Type | Description |
|---------------|------|------|--|
| ENABLE | 0 | rw | ENABLE the BPU 0_B BPU is disabled. 1_B BPU is enabled. <i>Note: This bit is set to 0 on Power-on reset.</i> |
| KEY | 1 | rw | KEY reads as 0 on reads, should be 1 for writes. If written as zero, the write to the register is ignored. |

| Field | Bits | Type | Description |
|-----------------|------------------|------|---|
| NUM_CODE | [7:4] | r | NUM_CODE , the number of breakpoint comparators. |
| 0 | [31:8], [3:2] | r | Reserved |

21.8.12 Breakpoint Comparator Registers

BP_COMPx

The BP_COMPx register holds a breakpoint address for comparison with instruction addresses in the Code memory region. A comparator can only be enabled when BP_CTRL.ENABLE is set to 1. BP_CTRL.NUM_CODE defines the number of implemented BP_COMPx registers, from 0 to (NUM_CODE-1).

The BP_COMP [3 .. 0] register are implemented.

BP_COMP0

Breakpoint Comparator X Register (008_H) **Reset Value: 0000 0000_H**

BP_COMP1

Breakpoint Comparator X Register (00C_H) **Reset Value: 0000 0000_H**

BP_COMP2

Breakpoint Comparator X Register (010_H) **Reset Value: 0000 0000_H**

BP_COMP3

Breakpoint Comparator X Register (014_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| ENABLE | 0 | rw | ENABLE the comparator 0 _B Comparator is disabled. 1 _B Comparator is enabled. <i>Note: This bit is set to 0 on a Power-on reset. BP_CTRL:ENABLE must also be set to 1 to enable a comparator.</i> |
| COMP | [28:2] | rw | Stores bits [28:0] of the comparison address. The comparison address is compared with the address from the Code memory region. Bits [31:29] and [1:0] of the comparison address are zero. <i>Note: The field is UNKNOWN on Power-on reset.</i> |
| BP_MATCH | [31:30] | rw | BP_MATCH defines the behavior when the COMP address is matched. 00 _B no breakpoint matching. 01 _B breakpoint on lower halfword, upper is unaffected. 10 _B breakpoint on upper halfword, lower is unaffected. 11 _B breakpoint on both lower and upper halfwords. <i>Note: The field is UNKNOWN on reset.</i> |
| 0 | 29, 1 | r | Reserved |
